2016; Yang et al. 2020; Watanabe et al. 2020). This camouflage and the negative charge it generates further prevent many of the immunogenic peptides from engaging the corresponding B cell receptors in order to effectively activate B cells producing anti-S protein antibodies. The studies described in this chapter on the amplification of the immune response to influenza virus and to gp120 of HIV suggest that glycoengineering of the inactivated SARS-CoV-2 or of its S protein to present α -gal epitopes is likely to increase their immunogenicity, as well (Galili 2020b). In addition to the elimination of the negative electrostatic charges surrounding the S protein (Figure 2), anti-Gal will form immune complexes with the vaccinating inactivated SARS-CoV-2 _{α gal} or with S protein _{α gal} and target these vaccines for effective uptake by APC via Fc/Fc receptor interaction (Figures 2B and 3). This extensive uptake of COVID-19 α -gal vaccines by APC will be followed by increased transport, processing and presentation of immunogenic S protein peptides within the lymph nodes, thereby increasing the probability of activation of the corresponding naive T and B cells in the elderly.

Glycoengineering of α -Gal Epitopes on COVID-19 Vaccines

Glycoengineering COVID-19 vaccines to present multiple α -gal epitopes may be achieved by a variety of methods. Some of these methods are described in this section:

- 1) *Neuraminidase and recombinant α 1,3galactosyltransferase synthesizing α -gal epitopes on whole virus or on S protein* – The method for synthesis of α -gal epitopes on the inactivated SARS-CoV-2 or on subunit and recombinant S protein is illustrated in Figure 1. Neuraminidase, α 1,3GT and UDP-Gal are available from commercial sources. In the studies on the glycoengineering of influenza virus or of gp120, the α 1,3GT was produced by cloning truncated New World monkey (marmoset) α 1,3GT cDNA lacking the cytoplasmic and transmembrane domains thereby allowing for secretion of the recombinant enzyme (Henion et al. 1994). The enzyme also had a (His)₆ tag which enabled its purification. The production of α 1,3GT was performed in *Pichia pastoris* expression system stably transfected with this cDNA in a plasmid used for this expression system (Chen et al. 2001). The secreted enzyme was isolated by passing the medium through a nickel-Sepharose column which attaches the enzyme via a (His)₆ tag, followed by elution with imidazole. In addition to synthesis of multiple α -gal epitopes on influenza virus and on gp120, this α 1,3GT was found to effectively synthesize α -gal epitopes on human tumor cells by the two step enzymatic reaction illustrated in Figure 1 (Chen et al. 2001; Galili et al. 2003; Furukawa et al. 2017) and on a variety of mammalian RBC and nucleated cells (Ogawa & Galili, 2006). Thus, it is probable that inactivated SARS-CoV-2 or its S protein, subjected to the enzymatic reactions in Figure 1, will effectively undergo a similar conversion of the SA carrying glycan shield to multiple α -gal epitopes presented on the glycans. Whereas the resulting inactivated SARS-CoV-2 _{α gal} can be isolated from the reaction mixture by precipitation or washing methods, the S protein _{α gal} can be purified by passing the reaction mixture through a

column of the lectin *Bandeiraea simplicifolia* IB4 linked to Sepharose or to other porous beads. This lectin binds specifically α -gal epitopes (Wood et al. 1979), thus it would bind the S protein _{α gal} and no other components of the reaction mixture. The bound S protein _{α gal} may be eluted from the washed column by free galactose, melibiose or α -methyl galactoside, which subsequently may be removed by dialysis. It is not known whether chemical linking of α -gal epitope to the S protein (e.g., linking of the trisaccharide via a spacer to lysins) is a suitable method because such linking may affect the specificity of the immune response against the native protein.

2) *Synthesizing α -gal epitopes on replicating SARS-CoV-2 virus-*

SARS-CoV-2 _{α gal} is by engineering the host cells to effectively synthesized α -gal epitopes on the S protein of the virus envelope. As discussed above, complex type glycans on the S protein, as those on other viral and cellular glycoproteins, are synthesized within compartments of the Golgi apparatus by a series of glycosyltransferases that add in a sequential manner carbohydrate units to the nascent carbohydrate chain on glycoproteins and glycolipids. Many of the glycans are “capped” with sialic acid which is linked to the glycan by sialyltransferases (SiaT), whereas the terminal galactose of the α -gal epitope is linked to the same glycan by α 1,3GT. Both glycosyltransferases reside within the trans-Golgi compartment and compete with each other for capping the glycan (Smith et al. 1990). The ultimate number of α -gal epitopes vs. sialic acid epitopes on a virus depends on the relative activity of α 1,3GT vs. that of SiaT. As shown in studies on activation of influenza virus specific T cells following anti-Gal mediated targeting of inactivated virus to APC, there is a correlation between the number of α -gal epitopes per vaccinating virus and the extent of T cell activation by peptides processed and presented by the APC (Galili et al. 1996). This suggests that by increasing the activity of α 1,3GT within the trans-Golgi of host cells, more α -gal epitopes will be synthesized on the glycan shield of the replicating virus. Thus, it is possible that stable transfection of the host cell line in which SARS-CoV-2 is propagated, with several copies of the α 1,3GT gene (*GGTA1*) will result increased activity of α 1,3GT. A high number of copies of this gene will elevate the amount of α 1,3GT thereby increasing the number of synthesized α -gal epitopes on the S protein of the replicating virus. This assumption is supported by studies demonstrating that measles virus replicating in human host cells transfected with the α 1,3GT gene present α -gal epitopes binding anti-Gal on their envelope glycoproteins (Preece et al. 2002; Dürrbach et al. 2007). A similar effect of increased number of α -gal epitopes on the virus may be achieved by disruption (i.e., knockout) of SiaT genes in host cells which will result in decreased competition of SiaT capping the glycans with SA and α 1,3GT thus, enabling α 1,3GT capping more glycans with α -gal epitopes. Since part of the glycans on the S protein are of the high mannose type, it is further possible that by disrupting genes associated with synthesis of high mannose glycans, more glycans will be synthesized as complex type glycans which enable additional synthesis of α -gal epitopes. Thus, an optimal host cell for production of SARS-CoV-2 with multiple α -gal epitopes may be a cell with several copies of the α 1,3GT gene, with reduced SiaT activity and possibly with reduced proportion of glycans of the high mannose type. It should be

noted that the glycans on SARS-CoV-2 also may affect the extent of replication of the virus in the host cell. Thus, following each genetic manipulation step of the host cells, the extent of virus replication should be determined in order to confirm that it was not affected. A similar approach may be considered for cell expression systems producing recombinant S protein and for cells producing SARS-CoV-2 virus like particles. All these vaccine materials may be produced with a large number of α -gal epitopes on the glycan shield in cells that have several copies of the α 1,3GT gene, disrupted SiaT genes and possibly disrupted genes of enzymes synthesizing high mannose glycans.

- 3) *Transduction with replication defective adenovirus containing the α 1,3GT gene for synthesis of α -gal epitopes on vaccinating viruses* – Multiple copies of the α 1,3GT gene may be introduced into host cells also by transduction with replication defective adenovirus containing the α 1,3GT gene (Deriy et al. 2002), prior to infection of the cells with SARS-CoV-2. Mouse α 1,3GT cDNA was inserted into a replication-defective adenovirus vector which lacks the E1 and E2 genes (Gao et al. 1996). This viral vector, designated Ad α GT, could be propagated in human 293 cells that have the viral E1 complementing gene. Transduction of human HeLa cells with Ad α GT resulted in immediate penetration of ~ 20 Ad α GT copies into each cell and the appearance of α 1,3GT mRNA after 4 hours (Deriy et al. 2002). Analysis of the appearance of α 1,3GT catalytic activity within the transduced cells at various time points demonstrated activity of this enzyme 6 hours post transduction. The α -gal epitopes were first detected on the cell surface glycans 10 hours post transduction. After 24 hours, each cell expressed $\sim 2 \times 10^6$ epitopes and after 48 hours the cells expressed a maximum number of 4×10^6 epitopes per cell. Thus, it is suggested that transduction of host cells with Ad α GT 12-24 hours prior to the infection of the cells with SARS-CoV-2 may result in effective synthesis of α -gal epitopes on the replicating virus. Since the number of complex type glycans vs. that of high mannose glycans may vary from one cell line to the other, a cell line producing virus with the highest number of glycans of the complex type may be preferable for intracellular synthesis of α -gal epitopes on SARS-CoV-2. Alternatively, glycoengineering the optimal cell line for decrease or elimination of high mannose glycans may require the inactivation of gene(s) associated with synthesis of such glycans. Glycoengineering of cells producing the S protein by methods suggested above for host cells producing replicating virus with maximum α -gal epitopes may also be applicable to the S protein producing cells.
- 4) *Production of S protein _{α gal} in glycoengineered yeasts*– Production of relatively large amounts of recombinant S protein _{α gal} may be achieved in yeast expression systems by stable transfection of the yeast cells with the S protein. However, in order to achieve synthesis of α -gal epitopes on the S protein product, yeast need to undergo additional glycoengineering manipulation since naturally, yeast have glycosyltransferases that can synthesize N-linked glycans only of the high mannose type. Glycoproteins which carry only the high mannose N-linked glycans have short half-life in humans. For production of glycoproteins with complex type glycans, yeasts such as *Pichia pastoris* have been glycoengineered to synthesize humanized

glycans with the terminal structure of complex type by introducing the corresponding glycosyltransferase genes (Choi et al. 2003; Wildt & Gerngross, 2005). In order to produce S protein with glycan shield presenting multiple α -gal epitopes, the *SiaT* gene in these yeasts may be replaced by the $\alpha 1,3GT$ gene (*GGTA1*). It remains to be determined whether such a manipulation is feasible and to what extent this expression system can produce sufficiently large amounts of S protein _{α gal} for preparation of a high number of vaccines.

- 5) *Production of S protein _{α gal} in glycoengineered bacteria* – Bacteria such as *E. coli* may also be engineered to produce S protein _{α gal}. Production of recombinant proteins in bacteria has been limited because of the difficulties in secretion of recombinant proteins beyond the periplasmic space into the culture medium. Secretion of such recombinant proteins has been achieved by the use of a nonionic detergent such as Triton X-100 (Fu, 2010). Secretion of a recombinant protein also could be achieved by modifying the protein for targeting it to the outer membrane and further into the extracellular medium (Fisher et al. 2011). Other studies have demonstrated biosynthesis of α -gal epitope oligosaccharides in *E. coli* by introducing into this bacterium genes coding for the sequence of mammalian glycosyltransferases including $\alpha 1,3GT$, required for α -gal epitope synthesis (Chen et al. 2000; Gebus et al. 2012). Moreover, *E. coli* was engineered to synthesize N-linked glycans by transfer into it an N-linked glycosylation system found in *Campylobacter jejuni* (Wacker et al. 2002; Fisher et al. 2011). It is suggested that combining these characteristics by introducing the genes coding for the above enzymes into one bacterial strain may lead to the production of an expression system that effectively produces S protein _{α gal} in quality and amounts suitable for vaccine preparation.

Potential Safety Issues with Future α -Gal Vaccines in Humans

Humans are regularly exposed to α -gal epitopes in meat such as beef, pork and lamb. However, relatively few individuals have been exposed to this epitope administered in the form of injection. This raises the question whether administration of vaccines presenting α -gal epitopes is safe in humans. The most common example of α -gal epitopes administration into humans in a form that is constantly exposed to the blood circulation is the replacement of impaired heart valves with bioprostheses of porcine heart valves or of bovine pericardium crosslinked by glutaraldehyde. Like other porcine and bovine tissues, these valves present multiple α -gal epitopes (Tanemura et al. 2000). No toxicity or other deleterious effects have been observed in association with this treatment which is widely used for replacement of impaired heart valves in elderly and young patients, respectively. Phase I clinical trials in which α -gal glycolipids are injected into solid tumors of cancer patients, in order to convert the tumor into autologous anti-tumor vaccines, also were found to be safe and demonstrated no adverse effects (Whalen et al. 2012; Albertini et al. 2016). Similarly, synthesis of α -gal epitopes on autologous tumor cell membranes followed by their incubation with anti-Gal and autologous dendritic cells, was performed for converting autologous tumors into vaccines.

Injection of such mixtures into patients was reported to be safe with no adverse effects, as well (Qiu et al. 2011; 2013; 2016).

A small proportion of individuals in various populations was found to produce anti-Gal IgE antibodies following the bite of several kinds of ticks including *Ambliomma Americanum* (Lone Star tick) in USA (Commins & Platts-Mills, 2013), *Ixodes ricinus* in Europe (Hamsten et al. 2013), *Haemaphysalis longicornis* in Japan (Chinuki et al. 2016) and *Ixodes holocyclus* in Australia (van Nunen, 2015). This IgE mediates allergic response to α -gal epitopes in meat is referred to as “ α -gal syndrome” (Wilson et al. 2017; Pollack et al. 2019). If viral vaccines presenting α -gal epitopes are developed for use in humans, it remains to be determined whether individuals with α -gal syndrome display adverse effects following administration of α -gal vaccine. In addition, vaccination of such individuals with α -gal vaccine will enable determining whether they require anti-allergy treatment prior to vaccination.

CONCLUSION

Production of the natural anti-Gal antibody in large amounts in all humans who are not severely immunocompromised, enables development of several novel immunotherapies. In these immunotherapies, the interaction between anti-Gal and the carbohydrate antigen it recognizes- the “ α -gal epitope,” may be applied for generating a variety of immune responses that can be beneficial to treated patients (Galili, 2013a; 2018). One of these applications is the amplification of viral vaccines efficacy by glycoengineering the glycan shield of glycoproteins on enveloped viruses to present multiple α -gal epitope and thus produce α -gal vaccines. Administration of viral α -gal vaccines in the form of inactivated whole virus vaccine, or of envelope glycoprotein vaccine results in formation of immune complexes with the natural anti-Gal antibody. This antibody is released from capillaries ruptured by the syringe needle at the vaccination site. The complement activation by such immune complexes results in generation of chemotactic peptides that recruit APC to the injected vaccine suspension or solution. This is followed by extensive endocytosis of the vaccine/anti-Gal immune complexes into the APC, instead of random suboptimal uptake by pinocytosis of standard non-immunocomplexed vaccines. The endocytosis is induced by interaction between the Fc portion of immunocomplexed anti-Gal and Fc receptors on APC and possibly between C3b attached to the immune complexes and C3b receptors (CR1) on APC. The internalized vaccines are processed within the APC and their immunogenic peptides are presented on cell surface MHC molecules. Transport of these vaccines by APC to regional lymph nodes results in activation of many virus specific helper and cytotoxic T cells which may effectively prevent the subsequent detrimental infection by the corresponding infectious virus. Studies in anti-Gal producing mice on the efficacy of α -gal vaccines, including inactivated whole influenza virus and recombinant gp120 of HIV, demonstrated 10-200 fold increase in the immune response with α -gal vaccines vs. vaccine lacking α -gal epitopes. Studies of challenge with a lethal dose of infectious influenza virus demonstrated 8 fold higher resistance to challenge of a lethal infection dose in mice immunized with α -gal vaccine than in the absence of α -gal epitopes on the vaccine. The α -gal vaccine method can further enable increasing immunity of internal viral proteins of low immunity by formation of fusion α -gal vaccines

between virus envelope glycoprotein and virus internal protein such as gp120_{αgal}/p24 of HIV which was found to greatly increase immunogenicity of both gp120 and p24.

The studies of influenza virus and gp120 α -gal vaccines strongly suggest that glycoengineering of SARS-CoV-2 inactivated whole virus and of this virus envelope S protein vaccines to present α -gal epitopes will markedly increase the immunogenicity and efficacy of these COVID-19 vaccines. This is because the number of N-linked glycans on the S protein is high, thereby ensuring the synthesis of many α -gal epitopes on the glycan shield of this envelope glycoprotein. Synthesis of multiple α -gal epitopes on SARS-CoV-2 or on S protein vaccines may be feasible by several methods. These include: *In vitro* enzymatic synthesis; propagating the virus in host cells engineered to contain many copies of the α 1,3GT gene (*GGTA1*) by stable transfection; transduction of host cells with replication defective Ad α GT virus; production of S protein_{αgal} in mammalian cell, yeast, or bacterial expression systems engineered to contain the glycosyltransferase transgenes required for the synthesis of α -gal epitopes.

Introduction of α -gal epitopes into humans, on glycans porcine heart valve or as glycolipids in cancer immunotherapy suggest that α -gal vaccines may be safe in humans. However, since a small proportion of humans display delayed allergic response to α -gal epitopes in meat (" α -gal syndrome"), it should be determined whether individuals with α -gal syndrome require anti-allergy treatment prior to receiving α -gal vaccines.

Chapter 381

THE MYOPIA EPIDEMIC - A WORLDWIDE VISUAL CONCERN

Angie Wen, MD, David MacPherson, MD and Neesurg Mehta, MD

Department of Ophthalmology, New York Eye and Ear Infirmary of Mount Sinai,
New York, New York, USA

ABSTRACT

Myopia is the most common ocular disorder worldwide. It is the leading cause of visual impairment in children, and the incidence is increasing rapidly. In 2010, an estimated 1.9 billion people (27% of the world's population) had myopia, 70 million of whom (2.8%) had high myopia, commonly defined as refractive error $\geq -6D$. These numbers are projected to rise to 52% and 10%, respectively, by 2050. Vision impairment related to myopia has significant effects on a patient's quality of life, including physical, emotional, and social functioning. Pathologic myopia (prevalence 0.9%–3.1%), which confers an increased risk of cataract development, retinal detachment, glaucoma, and even blindness, is particularly devastating.

Major economic impact has resulted from the increasing prevalence of myopia. Experts have estimated the loss in world productivity caused by uncorrected myopia in 2004 to have been 268.8 billion international dollars and the cost of addressing this problem to be US \$28 billion over 5 years.

Myopia is a particular public health concern in many East Asian countries, where the condition affects 80% to 90% of high school graduates. Of these individuals, 10% to 20% have sight threatening pathologic myopia. There appears to be not only environmental but also genetic factors that play a part in development and progression of myopia.

Initial research has shown that outdoor activity, sun light exposure, and low dose atropine all seem to help slow down the rate of myopia. It is theorized that visual input to the peripheral retina regulates adjacent scleral growth, and the relative peripheral hyperopic defocus in myopic eyes that remains despite wearing corrective myopic spectacles may be associated with elongation of the globe. Some have proposed using contact lenses that emphasize peripheral myopic defocus—and thus minimize hyperopic defocus—to help decrease progression of myopia. Similarly, there have been promising developments in technologies of lens spectacles to help slow down the rate of myopia. Perhaps the most exciting advancements have been in establishing efficacious dosing and

drug delivery of low dose atropine to the pediatric population. The concern for this global epidemic of myopia has spurred intense research efforts, and there are a number of promising avenues for prevention and treatment.

INTRODUCTION

Epidemiology

The global myopia epidemic and its attendant visual consequences have been well established. There is a race to ameliorate that rise as incidence across the globe continues to increase at an alarming rate. Myopia is the most common disorder of the eye as well as the leading cause of visual impairment in children [1, 2]. Patients with myopia experience difficulty with focus on distance objects without appropriate corrective eyewear, which can interfere with daily activities such as learning in school or driving safely.

Figure 1. The prevalence of myopia current % (projected % in 2050).

The World Health Organization (WHO) defines myopia as spherical equivalent objective refractive error of ≤ -0.50 diopter in either eye, high myopia as ≥ -5.00 D in either eye, and myopic macular degeneration as refractive error ≥ -5.00 D with specific retinal changes, or refractive error ≥ -10.00 D with or without retinal changes [3].

According to data compiled from 145 studies including 2.1 million subjects, an estimated 22.9% of the world population had myopia and 2.7% had high myopia in the year 2000, with the largest cohort between 10-39 years old [1]. In addition, by the year 2050 it is projected that a staggering 49.8% of the world population will be myopic, with 9.8% of them high myopes [1] (see Figure).

The myopia epidemic is of particular concern in certain East Asian countries. For instance, in China and Taiwan, the disorder is estimated to affect 80-90% of high school graduates, 10-20% of whom have vision threatening pathologic myopia [2, 4]. According to

Lam et al. the prevalence of myopia and high myopia in children age 6 was 18.3% and 0.7% respectively, and for those at age 12 was 61.5% and 3.8% [4].

In North America, the prevalence of myopia among high income families was estimated to be 28.3% in 2000 and projected to be 58.4% in 2050 [1]. In the United States, analysis of the IRIS (Intelligent Research in Sight) Data registry and the NHANES (National Health and Nutrition Examination Survey) data revealed diopter-adjusted prevalence of high myopia in 2014 to be 3.92% in 2014 with prevalence of pathologic myopia of 0.33% [5]. A cross sectional study of pediatric patients in Southern California by Theophanous shed light on the breakdown of myopia among age groups and race/ethnic background. Myopia was found to be more common in older children (59% in ages 17-19 versus 14.8% in those between 5 and 7 years of age) [6]. Household income was found to play a role as median households with income of \$25,000 -\$40,000 had lower rates of myopia compared to households with incomes less than 25,000 [6]. In addition, patients of Asian/Pacific Islander descent had an increased rate of myopia compared to their Caucasian and African American counterparts [6].

Wen et al. looked at the prevalence of myopia in a multi-ethnic pediatric eye disease study and found that non-Hispanic white children had the lowest overall prevalence of myopia compared to the other four racial/ethnic groups studied, whereas children of Asian descent had the highest prevalence [7]. However, no difference was found between gender in the children included in the study.

Sequelae of Myopia

There are significant visual complications associated with myopia, in particular pathologic myopia, which has an estimated prevalence of 0.9%-3.1% [3, 8]. Among the many sequelae are cataract, retinal damage including choroidal neovascularization and retinal detachment, glaucoma, and blindness. The WHO notes that the most common cause of vision impairment is undercorrected myopia likely from lack of access to providers and resources for corrective eyewear [3]. While corrective eyewear can remedy simple myopia and cataracts can be removed with surgery, the peripheral vision loss that occurs with glaucomatous optic nerve damage and the central vision loss that occurs with Myopic Macular Degeneration [MMD] of the retina is unfortunately permanent. Glaucoma involves progressive damage to the optic nerve fiber layer and loss of peripheral vision that can eventually affect central vision if left untreated. MMD can be seen clinically as either patchy or diffuse chorioretinal atrophy. In advanced cases, abnormal blood vessel development, known as choroidal neovascularization (CNV), can develop in the fovea of the retina, which is responsible for central vision [3]. These abnormal blood vessels leak blood and proteins into the surrounding retina and can cause vision loss and distortion. The prevalence of CNV in individuals with MMD is estimated to be 5.2% to 11.3%, and can be bilateral in 30% of patients. Macular holes, which can be particularly damaging to central vision, can occur in 6% to 8% of these cases [8, 9].

As previously mentioned, the burden of disease is increased in patients of Asian descent. An estimated 1% of Caucasian compared to 1-3% of Asians counterparts have pathologic myopia [3, 8]. Furthermore, pathologic myopia in Asians leads to more visual impairment and blindness compared to Caucasians [3, 8].

Financial Burden of Myopia

The myopia epidemic also has significant global economic consequences. Poor vision resulting from myopia leads to loss of work force and inefficiencies in the work and home environment. According to Fricke, uncorrected refractive error contributes to a loss of \$202 billion of the global gross domestic product [10]. In addition, it is estimated that there was a loss in world productivity of 268.8 billion international dollars in 2004, and it cost 28 billion US dollars to address the issue [11]. The astounding burden disproportionately affects people from low-income families [12]. Additionally, a study by Ma et al. in China suggests that providing access to refractive correction in low socioeconomic areas would improve educational outcomes in children [13].

In Singapore the direct cost attributed to remedy myopia per child per year is estimated to be \$148 US dollars [14]. Zheng et al. looked at 125 myopic patients and found the mean cost per person per year was \$709 US dollars and a lifetime per capita cost of \$17,020 for those with an 80-year lifespan. A breakdown of the cost estimate includes such services as glasses, contact lenses, refractive surgery, and overall ophthalmologic services [15].

PATHOGENESIS

Onset/Progression

The onset of myopia seems to increase significantly after the age of 6. This increase has previously been linked in studies to the beginning of school and attendant increase in near work and hours spent studying [16, 17]. The prevalence rate of myopia in subjects less than 6 years of age tends to be less than 5% even in areas of high burden such as East Asia [18-21]. However, the incidence in even this very young population is increasing as well. Fa et al. found an estimated increase in myopia of 6.3% from 2.3% over 10 years among Hong Kong preschoolers [22].

In Chinese populations the annual incidence of myopia between the ages of 7-15 years has been relatively constant with up to 80% of certain subpopulations suffering from myopia [23]. Studies show comparable patterns in other East Asian countries, with increased incidence at even younger ages suggested in Singapore, Taiwan, and Hong Kong [24-26]. Western countries seem to fare better, with meta-analyses showing a much lower childhood incidence of myopia with a later age onset as well [27]. Rahi et al. reported that most cases of myopia identified in the United Kingdom were in children 16 years of age or older [28].

The meta-analysis performed by Rudnicka et al. reported that populations in South Asia, black populations in Africa, and Hispanics tended to have lower prevalence of myopia than Western white populations, whereas black populations outside of Africa, South-East Asians, Middle Eastern/North African populations, Native Hawaiians, and American Indians have a higher prevalence [27]. All these groups still have significantly lower incidence of myopia compared with East Asian populations [27].

Environment

The alarming rise of myopia has led investigators to work to uncover modifiable risk factors for myopia in order to engage in early prevention. Multiple risk factors contributing to the development of myopia have been postulated. Among those explored are time spent outdoors, near work, and a societal shift to dependence on phones, tablets, and computers.

At the current time, the predominant protective environmental factor seems to be time spent outdoors. A potential dose dependent relationship has been researched between the amount of time spent outdoors and the risk of myopia [29, 30]. In a systematic review Xiong et al. looked at the relationship between outdoor time with the incidence of myopia as well as progression in already myopic eyes. There was a protective effect against myopia *onset* with increased time spent outdoors. Unfortunately, there was no effect on slowing progression in patients *already* myopic [29]. The study elucidated the need for further investigation on the subject including optimal time outdoors and strategies for implementing this protective environmental factor. The authors acknowledged multiple limitations of the study including retrospective nature and high heterogeneity among the studies analyzed.

The hypothesized mechanism of protection of time spent outdoors include biochemical activity, a uniform dioptric space, relaxed accommodation and increased pupil constriction, as well as physical activity [30]. Light stimulated retinal release of dopamine and other neurotransmitters that inhibit increased axial length may serve as the biochemical mechanism for decreased myopia with outdoor activity [30, 31]. This has been supported to some degree in certain animal studies while other mechanisms explaining outdoor time protection have had less of an impact [30, 31]. Outdoor sports and other physical activity have been theorized to contribute to decreased incidence of myopia. Interestingly, a study by Rose et al. found that there was no association between participating in indoor sports and myopia [32]. Further studies attempting to separate the factors of increased light exposure and outdoor/indoor activity would be of great interest in guiding recommendations for children and physical education classes in school.

Near Work

Another environmental factor highly investigated in association with myopia is near work. The definition of and means of measurement of near work has been highly variable among different studies. This included level of education, duration of sustained study time, duration of leisure reading, books read per certain amount of time, font size, and screen use [33].

Near work as a cause of myopia is especially problematic given that over the last two decades, daily routine in many developed countries has shifted exponentially towards the reliance on digital formats for work, leisure, and activities of daily living. Much of this digital content is consumed on screens at arm's length, such as on smartphones and desktop or tablet computers. Communication has transitioned heavily to texting, emails, and video usage, all which require sustained near work activity. This dependence on screen time contributes to increased cumulative near work hours. Huang et al. found in a systematic review and meta-analysis of 12 cohort studies and 15 cross-sectional studies that increased time spent

participating in near work activity was associated with higher odds of myopia, and that the odds of developing myopia increased by 2% for every additional diopter-hour of near work performed per week [34].

Even more worrisome is the fact that children are introduced to screen time via phones and tablets at a younger and younger age as forms of early education and entertainment. The Sydney Vascular and Eye Study (SAVES) was a 5 to 6 year follow up study of 2103 children that showed an increased odds of incidence of myopia by age 12 for those children with short periods of time outdoors and longer duration and frequency of near work [30]. A Study in Shanghai by You examined the relationship between various near work activities among 6-to-10-year-old children and myopia over a one year follow up [35]. In the study, the participants and their parents filled out a questionnaire together on nine different near work factors in addition to baseline eye exams which included measurements such as axial length and cycloplegic refraction at baseline and one year follow up. They reported on various factors that were associated with increased myopia as measured by both cycloplegic refraction and axial length biometry. These included use of an inappropriate distance with the eye while reading, writing, or engaging in TV screen time, poor lighting while reading or writing, and continuous near work greater than 30-40 minutes without an eye break [35].

The Covid19 pandemic and the attendant recommendations for social distancing have resulted in a shift to working from home for many adults, and remote learning for children, resulting in an exponential increase in screen time for both groups. There is great concern that a semi-permanent switch to digital classrooms can have a devastating acceleration in the rise of myopia in young children. Currently, the WHO and the American Academy of Pediatrics recommend no screen time at all for children younger than 2 years of age, and less than 1 hour a day for children 2 to 5 years old [36]. More studies are required in the future to study the effects of digital near work on children and adolescents, especially those of handheld devices.

Genetics

Genetic factors and heritability have also been explored in the development of myopia. More than 150 gene loci associated with myopia have been identified in genome-wide association studies [37]. A study by Chen reported nine gene loci that were associated with axial length *RSPO1*, *C3orf26*, *LAMA2*, *GJD2*, *ZNRF3*, *CD55*, *MIP*, *ALPPL2*, and *ZC3H11B* [38]. The researchers organized the mentioned loci into two groups. The first group includes loci involved in the Wnt signaling pathway related to the regulation of axial length (*RSPO1* and *ZNRF3*). The other group includes 5 loci that were found to be associated with common refractive error variation *LAMA2*, *GJD2*, *CD55*, *ALPPL2*, and *ZC3H11B*.

A meta-analysis by Sanfilippo reported that heritability for refractive error was 0.71 [39]. Other heritability estimates from studies have ranged from 0.11 to 0.98, the higher estimate coming from a study of Finnish female twins [40]. Although many gene loci have been identified, genetic risk scores estimate they only explain 0.6% of the variance in refractive error at age 7 and only 2.3% at age 15 [43].

Family history of myopia has also been investigated. Zhang et al. summarized in a meta-analysis an association between the number of myopic parents and incident myopia [43]. The

odds ratios calculated in this analysis ranged from 1.44 to 2.96 for having a myopic child depending on the number of myopic parents [43]. Another study of Chinese students found that there were 26-fold higher odds for prevalent myopia in students with close reading distances and two parents with myopia [44]. However, family history as a risk factor has further indications, particularly in light of increased myopic prevalence. Xiang comments that the odds of a child becoming myopic with two myopic parents is different than the odds of a myopic child having parents that are both myopic because there are likely more children than parents with myopia [45]. Thus, the sensitivity of parental myopia in predicting childhood myopia remains weak [46].

TREATMENT

Contact Lenses

It is theorized that input to the peripheral retina regulates adjacent scleral growth, and in turn the peripheral hyperopic defocus associated with globe elongation and thus myopia [47, 48]. Consequently, there is interest in using contact lenses that emphasize peripheral myopic defocus to help counteract hyperopic defocus and to decrease myopic progression. Early studies have been promising, with Lam of Hong Kong finding a 25% slower progression of myopia with specialty bifocal defocus-incorporated soft contact lenses compared with single-vision soft contact lenses. This treatment effect had a positive correlation with length of time the defocus-incorporated soft contact lenses were used [49].

A review by Bullimore looked at multiple treatment methods researched in the prevention of myopia, including soft contact lenses that alter central distance zone and provide increased peripheral retina positive power [50]. Variables manipulated among studies included lens design, amount of power provided by the lens periphery, spherical area of positive power, multiple concentric treatment zones, and spherical aberration. They concluded that while single vision soft contact lenses were not recommended in myopic children, multifocal and orthokeratology lenses could potentially become the standard of care for preventing myopic progression in children and adolescents.

A study by Walline looked at progression of axial length and myopia among eight-to-eleven-year old children fitted with distance center soft multifocal contact lenses over a two year period [51]. It was found that myopia and axial length progression were decreased in participants by 50% and 29% respectively. Another study found similar progression reduction in dual-focus soft contact lenses among participants eleven to fourteen years of age. It was reported that in 70% of the children enrolled in the study, myopic progression was reduced by 30% in those assigned to dual focus lenses [52].

A study among Chinese children ranging from ages seven to fourteen by Sankaridurg found that reducing relative peripheral hyperopia with contact lenses can slow progression of axial length and myopia as well [53]. They reported that the spherical equivalent at 12 months was 34% less (-0.57D in contact lenses versus -0.86 D glasses) and that axial length was 33% less in those in the contact lens group.

Orthokeratology

Orthokeratology involves the placement of a hard gas permeable contact lens overnight to temporarily alter the cornea curvature to improve visual acuity throughout the day. Previous studies have shown temporary improvement of visual acuity, though there is expected regression of the majority of the effects during the day when the lens is not worn. Current research focus has turned to the potential of orthokeratology in reducing myopic progression. A randomized trial of 78 participants by Cho and Cheung over a two year period found a reduced increase in axial length by 43% in those assigned to orthokeratology compared to those wearing single-vision glasses over time [54]. In addition, it was reported that younger participants had faster rates of axial elongation suggesting earlier initiation of treatment. A study by Li estimated the two year reduction in axial length progression to be around 0.28mm [55].

A study by Santodomingo-Rubido looked at the increase in axial length over a seven year period in a group of subjects wearing orthokeratology lenses compared to controls. Rate of change in axial length was reported to be 33% less in those patients using orthokeratology lenses [56]. Another prospective study over five years found a statistically significant difference in axial length between orthokeratology versus control groups [57]. Axial length during the 5 years was 0.99 ± 0.47 for the orthokeratology group and 1.41 ± 0.68 mm for the control group. It must be noted that there are considerable safety concerns associated with orthokeratology including but not limited to the potential for blinding microbial keratitis associated with overnight contact lens wear, and thus the use of orthokeratology at all is still considered controversial in many medical ophthalmologists [58, 59].

MiSight

MiSight dual-focused optical design soft contact lenses by Cooper Vision (USA) are the first contact lenses approved by the FDA for reducing myopia in November 2019. The study performed in 2018 showed a significant slowing of the progression of myopia and axial length over a four year time period including in children starting use at later ages [60].

A three year multicenter randomized clinical trial of MiSight lenses was conducted by Chamberlain comparing the dual-focus MiSight lens with a single-vision contact lens of the same material and general geometry. Overall, it was reported that MiSight was effective in slowing the progression of spherical equivalence and axial length in the participants ages eight to twelve years old. Spherical equivalent refraction was found to be 59% less in the MiSight group than the control group (-0.51 ± 0.64 vs. -1.24 ± 0.61 D, $P < .001$) [61]. In addition, mean change in axial length was also found to be 52% less in the MiSight group (0.30 ± 0.27 vs. 0.62 ± 0.30 mm, $P < .001$). A two year study performed in Spain by Ruiz-Pomeda looked at MiSight compared to single vision contact lenses, and reported similar findings that the MiSight group had a slower progression of myopia and decreased axial elongation compared to the control single-vision contact lens wearers [62].

Spectacles

Glasses have also been an area of interest in efforts to slow the myopia epidemic, though many studies have not found clinically significant reductions. The COMET (Correction of Myopia Evaluation Trial) was a landmark study that compared progression of myopia in subjects using progressive addition lenses (PALs) and single vision lenses. PALs are lenses that have a blended bifocal design with the top segment of the lens used for distance focus, and progressively positive lens power towards the bottom of the lens with corresponding shorter and shorter focal points. It was found that myopia progression was slowed in subjects in the PALs group compared to the group with single vision lenses. A 5 year follow up of the COMET study found only a small statistically significant difference between the groups that was present only during the first year [63]. Edwards reported a similar disappointing finding in progressive addition lenses versus single vision lenses. After two years they found that there was no difference in axial length or myopic progression between the two groups [64].

Bifocal glasses have also been evaluated in reducing accommodative lag and hyperopic focus to reduce myopia. In a three year randomized control trial by Cheng et al. subjects were assigned to one of three groups, single vision glasses, +1.50 D bifocals, or +1.50 bifocals with 3 D base down prism in the near segment. It was reported that both bifocals and prismatic bifocals significantly slowed myopia progression compared to single-vision lenses during the study time period [65]. Average spherical equivalents reported over the three years were -2.06 D for single-vision lens, -1.25 D for bifocal, and -1.01 D for the bifocal plus prism group.

Other research in spectacles is ongoing, many through innovative biotech companies. SightGlass Vision (USA) is currently working on developing novel spectacles aimed at slowing myopia progression in children. The CYPRESS (Control of Myopia Using Peripheral Diffusion Lenses: Efficacy and Safety Study) trial is an ongoing multicenter, double-masked, randomized controlled clinical trial that is looking to measure myopia progression over the course of 36 months using novel lens designs [66].

The Defocus Incorporated Multiple Segments (DIMS) spectacle lens (Hoya Vision, Japan) is a specialized lens that features a central optical zone that corrects refractive error and includes multiple microlenses around the central zone and extending to the midperiphery that produce constant myopic defocus. A 2 year double masked randomized controlled trial by Lam et al. looked at 160 Chinese children aged 8 to 13 years who had between -1.00 and -5.00 D of myopia and 1.50 D or less of astigmatism. The results showed that children wearing DIMS lenses myopia progressed 52% slower and had 62% less axial length elongation compared to the single vision glasses group over the two year period [67]. Furthermore, seventeen of the 79 children (21.5%) in the DIMS group and six of the 81 children (7%) in the single vision group had no myopia progression during the 2-year study.

Atropine

Medical therapy has been at the forefront of myopia prevention, with the antimuscarinic agent atropine being an especially promising medication under investigation. Atropine is a cycloplegic agent that dilates the pupil and restricts accommodation. Accommodation is the

process by which the eye changes from distance focus to near focus, and involves changes in the natural eye lens shape and contraction and relaxation of the ciliary muscle. Although the exact mechanism of action of slowing myopic progression is unclear, some postulate an anti-muscarinic impact on receptors in scleral fibroblasts that slow axial length elongation [68, 69].

A study by Shih from 2001 was important in showing that atropine had a greater therapeutic effect for myopic progression than glasses. In this randomized clinical trial, the results from 188 myopic children assigned to three groups 0.5% atropine with multi-focal glasses, multifocal glasses, and single vision spectacles over an 18 month period were provided. Main conclusions from the study were that myopia progression was significantly correlated with increased axial length, those assigned to the 0.5% atropine and multifocal lens group had a significant reduction in myopia progression, and that multi-focal lenses failed to show difference in effect compared to control [70].

The ATOM1 (Atropine for Treatment of Childhood Myopia study) by Chu et al. looked at 346 children aged 6 to 12 over two years who were randomly assigned to 1% atropine drops or control vehicle drops. There was a reduction in progression of myopia of -0.92D and reduction in axial length elongation of 0.40mm in groups treated with atropine 1% compared with control [68]. ATOM2, a follow-up study, further investigated the effective dose-dependence of atropine in preventing myopia progression [69]. 400 children were randomly assigned in a 2:2:1 ratio to 0.5%, 0.1%, and 0.01% atropine drops. Mean myopia progression at 2 years was found to be -0.30 ± 0.60 , -0.38 ± 0.60 , and -0.49 ± 0.63 D in the atropine 0.5%, 0.1%, and 0.01% groups, respectively, and the mean increase in axial length was 0.27 ± 0.25 , 0.28 ± 0.28 , and 0.41 ± 0.32 mm respectively [69]. Differences in myopia progression and axial length between groups however were not found to be clinically significant. Furthermore, it was found that there was a rapid rebound increase in myopia when atropine was stopped for 12 months after the 24 months of study treatment. The group receiving atropine 0.01%, had the least rebound effect and had minimal side effects compared to the 0.1% and 0.5% groups, suggesting extended efficacy of a low-dose of atropine [69] (see Table).

Study	Year/Authors	Key Findings
An intervention trial on efficacy of atropine and multi-focal glasses in controlling myopic progression	2001/Shih et al.	0.5% atropine with multi-focal lenses can slow down the progression rate of myopia Multi-focal lenses alone showed no difference in effect compared to single vision lenses (control)
Atropine for Treatment of Childhood Myopia study (ATOM1)	2006/Chua et al.	Reduction in progression of myopia of -0.92D and reduction in axial length elongation of 0.40mm in groups treated with atropine 1% compared with control
Atropine for the treatment of childhood myopia: safety and efficacy of 0.5%, 0.1%, and 0.01% doses (Atropine for the Treatment of Myopia 2) (ATOM2)	2012/Chia et al.	Differences in myopia progression and axial length change between groups were small and clinically insignificant Atropine 0.01% has minimal side effects compared with atropine at 0.1% and 0.5
Five-Year Clinical Trial on Atropine for the Treatment of Myopia 2: Myopia Control with Atropine 0.01% Eyedrop	2016/Chia et al.	Medications were stopped for 12 months after the initial 24 months of study treatment, and the group receiving atropine 0.01%, had the least rebound effect and had minimal side effects compared to the 0.1% and 0.5% groups
The Low-Concentration Atropine for Myopia Progression (LAMP) Study: Phase 2 Report	2020/Yam et al.	0.05%, 0.025%, and 0.01% atropine eye drops were all well tolerated and reduced myopia progression along a concentration-dependent response 0.05% atropine was most effective in controlling spherical equivalent progression and axial elongation

The more recent LAMP (The Low-Concentration Atropine for Myopia Progression) study took a closer look at even lower doses of atropine, investigating safety and efficacy of atropine at 0.05%, 0.025%, and 0.01% concentrations compared to placebo over a 1-year period [71]. Subjects were randomly assigned in a 1:1:1:1 ratio to receive 0.05%, 0.025%, 0.01%, or placebo nightly. All atropine concentrations were found to slow myopic progression, with the 0.05% being the most effective in reducing progression of both spherical equivalent and axial length elongation [71].

A recent randomized clinical trial conducted by Wei et al. in published in October 2020 sought to determine the safety and efficacy of atropine 0.01%. 220 Chinese children aged 6 to 12 were randomly assigned in a 1:1 ration to atropine 0.01% or placebo groups. Results after 1 year showed a relative reduction of myopic progression of 34.2% and 22.0% in axial elongation in the group receiving 0.01% atropine [72].

Since the ideal window for treatment for myopia prevention appears to be in the pediatric age group, there is also a push to research novel methods of medication administration to make it more tolerable for children, who often find eyedrop application uncomfortable. The Optejet dispenser by EyeNovia (USA) uses piezo-print technology to allow children to self-administer 8 μ L of atropine in order to minimize dose-related side effects [73]. Their ongoing CHAPARONE study, a US-based phase 3 multicenter, randomized, double-masked study, seeks to investigate the safety and efficacy of the Optejet dispenser, enrolling more than 400 children.

Pirenzepine

Another drug being investigated for myopia prevention is pirenzepine, a relatively selective antimuscarinic M1- receptor antagonist. Atropine is a nonselective antimuscarinic agent. A study by Siatkowski randomized children aged 8 to 12 years in a 2:1 ratio to receive 2% pirenzepine ophthalmic gel or placebo twice daily. At 1 year, the mean increase in myopia om the pirenzepine group compared to control was 0.26 D and 0.53 D respectively. At 2 years, the mean increase in myopia was 0.58 D and 0.99 for the pirenzepine group and the placebo group respectively [74].

CONCLUSION

The myopia epidemic is sweeping the globe at an alarming rate with potential visual consequences that impact productivity and individual quality of life. With such profound visual, social, and economic consequences, the importance of mitigating progression has never been greater. Further research needs to be conducted on modifiable environmental risk factors, genomics, and medical therapy. Higher near work demands in our increasingly digital world threatens to accelerate the rise in prevalence of myopia. Dual zone contact lenses and other specialty contact lenses and spectacles seem to be promising treatments. Atropine in particular is a major focus of pharmacological treatment. In addition, continued innovation in providing therapy and reaching those communities most at risk must be implemented.

Chapter 382

WHICH DEMOGRAPHIC QUINTILE BENEFITS FROM PUBLIC HEALTH EXPENDITURE IN NIGERIA: A MARGINAL BENEFIT ANALYSIS*

Kanayo Ogujiuba[†], PhD and Nancy Stiegler, PhD

Statistics and Population Studies Department, University of the Western Cape,
Cape Town, South Africa

ABSTRACT

In the last twenty years, policy makers have come to an understanding that for poverty reduction to be sustainable and welfare benefits distributed evenly, social investments must act as a catalyst. Thus, no meaningful progress in sustainable development can be made when the level of inequality level is continuously rising and benefits of government expenditure unevenly shared. At the moment, Nigeria is one of the twenty poorest, most unequal societies in the world, with just half of the population controlling 5 percent of national resources. Productive sectors in Nigeria have considerably shrunk in size since the 1980s, to the extent that about 70 per cent of the population lives below the poverty line, which is deep, severe and pervasive. This raises concerns and questions on demographic dividends from investments in the social sector. Data for research was obtained from ministries of health as well as private service-providers in the SE region of Nigeria. Marginal Benefit Incidence Analysis was used in estimating the benefits of various quintiles by combining information about unit costs of providing services with information on the use of these services. Thus, this chapter focused on the distribution of beneficiaries across different demographic groups from services rather than measuring the exact value to recipients of government-sponsored services. Results indicate that the states in the South East (SE) Nigeria subsidized the rich in the society. The chapter recommends effective discretionary targeting of expenditure, and the less privileged in government expenditure programmes. This is a potent strategy for curtailing poverty and inequality in the system and would serve as a means of sustaining societal growth and economic progress.

1. SOCIAL INVESTMENTS AND POVERTY REDUCTION

In most developing countries, Nigeria inclusive, government forms a large bulk of economic activity (Agu and Aldo, 2013) and one major challenge to government at all levels is the decision they make in organizing and distributing resources. However, the nexus between government expenditure and economic growth has been debated constantly among scholars. This includes protection and security of lives and properties and the provision of public and social goods such as defense, good roads, education, and health. Thus, government allocates resources to perform these basic functions, while some scholars argue that an increase in government expenditure promote growth (Al-Yousif, 2000; Ranjan and Sharma, 2008; Cooray, 2009), others argue that government expenditure undermines economic growth (Laudua, 1986; Engen and Skinner, 1992; Folster and Henrekson, 2001). For the last two decades, poverty reduction and public expenditure nexus have taken the center stage (Aigbokhan, 2000), with no agreeable framework on the dynamics.

Over time, economists and demographers have come in agreement that for even benefits across population groups, poverty reduction to be sustainable, social investments in education and health sector should be given high priority. Furthermore, Addison and Cornia (2001) suggest that no meaningful progress in sustainable development can be made when the level of inequality level is continuously rising, which is in contradiction with earlier development theories that inequality is good for growth and poverty reduction. This dichotomy is calling attention to the actual role of health infrastructure in economic growth vis-à-vis poverty reduction. However, much of contemporary debate on the nexus between public expenditure and demographic dynamics has been on what is the right size for a population and implications for standards of living and no emphasis on who gets what, when and how. No doubt, that the efforts by most populous countries to provide an acceptable living condition in terms of social services are constantly frustrated with rapid population growth, without a commensurate increase in economic growth. Therefore, the benefit incidence amongst the different quintiles becomes very pertinent.

The relationship between inequality, poverty and demographic dividends from public health expenditure is part of a larger cycle, where inequality and poverty leads to ill health and ill health due to lack of any substantial benefits sustains the twin evils. Available statistics suggest that people in emerging and transition countries tend to have less access to health services than those in better-off countries, and within countries, the poor have less access to health services. Although a lack of financial resources or information can create barriers to accessing services in developing countries, the causal relationship between benefits to health services and poverty also runs in the other direction. When health care is needed, but is delayed or not obtained, people's health worsens, which in turn leads to lost income and

higher health care costs, both of which contribute to negative outcomes. Lack of health care dividends by the vulnerable could lead to ill health, and worsened poverty levels¹.

Nonetheless, Nigeria has become a reference point for high inequality, economic growth and poverty levels. This has become so, more especially since the oil boom of the 1970s and the current rebasing (2014) of the Nigerian Economy, making it the biggest in Africa. This development paradox stands out when compared with similar comparable countries in Africa and Asia based on their collective history. The current per capita income in Nigeria is still very minimal in real terms and less than the 1975 estimate, despite the receipt of about two hundred and eighty-eight million dollars (USD288) in total oil revenue from 1975 to 2010². Adejuwon and Adekunle (2012)³ sums it up that about 70 per cent of the population lives below the poverty line and poverty is deep, severe and pervasive in the country. At the moment, Nigeria is one of the twenty poorest, most unequal societies in the world, with just half of the population controlling 5percent of national resources (Temitope, 2008). This raises the question of what has happened to all the investments in the social sector and who is benefiting from government expenditure.

Bridging the income margin between the rich and the poor as well as the efficient allocation of resources is necessary as part of a larger strategy to design and implement a sustainable developmental framework. Ogundipe and Lawal (2013) maintain that such a design would reduce poverty to some extent, especially if funds are well targeted towards health and education. Nonetheless, households in Nigeria are divergent in their ability to access and utilize services provided by the government (Diejomaoh and Eboh 2010). Most often, it is households in the upper income group which may reap larger benefits from public spending (health and education) programs (Suberu 2001). As a palliative to expenditure cutback, Ravallion (2002) argues positively for safety net measures, which would reduce the negative effects on expenditure, more especially on the vulnerable. One of such could be an effective targeting of health expenditure across different population groups.

According to Obansa et al. (2013) and retrieved from www.mcer.org, basic life-saving commodities are in short supply in lower income health systems. In these countries, provision of health related services depends on the availability of relevant equipment, drugs and infrastructure. Therefore, in the light of this, a constant and fundamental component of health management is an effective and accountable framework for procurement. In most states of Nigeria, several health facilities are without portable drinking water, electricity, dysfunctional equipment, etc. Health system is grossly inadequate, most especially at the Primary Health-care level (Obansa and Orimisan, 2013). Furthermore, poor state of infrastructure such as buildings, materials, equipment, and supplies and inequitable distribution of available facilities is the norm in many places in Nigeria.

Furthermore, uncertainty of drug supplies, which is common across the country and lack of basic amenities, has been traced to importation dependency of the health system in the country. The lack of updating of the pharmaceutical regulations could also be responsible for this ambivalence which has resulted in a complete chaotic drug distribution framework in the country. A clear negative fall-out of this scenario is the observed resistance to some drugs by

¹ The vulnerable in most of sub-Saharan Africa is particularly at risk.

² Furthermore, the productive sectors of the economy have considerably shrunk in size since the 1980s.

³ Poverty is also becoming *dynastic* in Nigeria—with the threat that the children of the poor are also likely to end up poor (Ehigiene 2007).

the disease pathogens in some patients (HERFON, 2006, FMOH, 2004, Travis et al., 2004). Nonetheless, without functional health facilities and qualified personnel, the availability of drugs alone would not improve the quality of health service. Vital to the provision of a functional health system is the former. However, it is common knowledge that in most communities in Nigeria, people travel several kilometers for basic health care services and in some case if not most, some these facilities are based on political expediency rather than economic rationality because they lack adequate professionals. Poor services at public health institutions in Nigeria have prompted the use of unorthodox medicines by most people, and for the privileged rich, the use of private health facilities (Ravi Rannan-Eliya, 2008), in addition to government hospitals.

The Nigerian government has been resorting to social spending discretions to alleviate poverty, thus it has become imperative for the government to understand the distributional outcomes from such expenditure. Marginal Benefit Incidence Analysis has assumed a center stage in most policy evaluations. The technique is normally used in assessing the distributional impact of government expenditure in addition to determining which demographic group benefits from the government (cash or in-kind). The underlying framework is that benefits derived from government expenditure should be shared disproportionately so that the lowest strata benefits more than those on a higher quintile. This implies that government spending according to the Keynesian model, should correct failures in the system, while promoting efficiency and equitable distribution of resources.

2. CONCEPTUAL FRAMEWORK

Fan, Zhang, and Zhang (2002) report that social expenditure reduced the rural poverty rate effectively. Jung and Thorbecke (2003) study also confirms that government social sector spending contributes to economic growth and supports poverty reduction. According to Lipton and Ravallion (1995), the poor that had less access to the infrastructure in the past can have larger benefits from new investment in health infrastructure. They came to this conclusion from their study on the effects of government expenditure on poverty. Also, in a study by Jung, et al. (2009) the marginal effects of government expenditures on poverty alleviation has generally weakened over time. Their analysis stands out in two ways: (1) contributes to the expanding literature on effects of government expenditure on poverty reduction by determining how the effects on poverty of four categories government expenditures have changed over time and compared these changes among categories; and (2) the study analyzed spatial variation in the effects of government expenditure on poverty across counties using GWR and LISA clustering. Their analysis further examined marginal effects of government expenditure on poverty reduction in each of the identified poverty clusters including the identification of poverty 'hot-spots'.

There are divided opinions and findings on the relationship between public sector spending and economic performance though most scholars are in agreement that there are circumstances in which decreased government spending would enhance economic growth and other circumstances in which increased government spending would be sought-after. Therefore, the connection between economic growth and government spending is bi-directional, particularly with growth and sectoral outcomes, in that higher growth leads to

improved sectoral outcomes (better schools, health indicators, road access, etc.) while enhanced sectoral outcomes will correspondingly lead to superior growth (in particular investment in health education and infrastructure is associated with higher growth rates). Looking at the theoretical underpinnings of public spending effects, it becomes imperative to look at the motive and its linkages with economic growth, poverty and inequality reduction for it to have the desired effect on distributional outcome.

Available literature suggests that exceptional variables which could hamper or effect positively public spending outcome are the roles of regulatory framework and private sector interventions because of their multiplier effect on service provision to the poor. According to Wilhelm and Fiestas (2005) government spending is driven by the objective to positively affect growth and poverty reduction through improved provision of social services. However, achieving this objective depends to a great extent on specific issues and initial conditions within a country.

Source: Adapted from Wilhelm and Fiestas 2005.

Figure 1. Public spending motives, determinants and linkage with growth and poverty reduction.

Figure 1 above shows the linkage which indicates that motives (political, economic, social, etc.) have effects on public spending while capacity and institutional constraints do affect motives behind public spending. The diagram also shows that effective and efficient outcomes could be determined by spending level; demographics; level of urbanization; complementarity; sub-sectoral mix; strength of institutions; the level of participation for private and NGO sector as well as time lags.

The relationship between public spending and poverty has gained sufficient attention in the literature and Economists are in agreement that expenditure on growth drivers has the capacity to reduce poverty and increase human capabilities. Asghar, et al. (2012) posits that economic growth and poverty reduction could occur with government spending on the social sector which would positively affect economic development. Nonetheless, investments in health, education and generally on the social sector were the mantra in the 1990s for the World Bank in its poverty Reduction Strategies Programmes. They argued that boosting

human capital formation reduces the level of poverty. Human resources according to the World Bank enrich human capabilities and productivity level of the people, which has the capacity to reduce poverty and increase income level through improved opportunities. Their results imply a positive reduction of poverty as expenditure is focused on social issues and the opposite when expenditure is focused on deficit financing, economic and community services in Pakistan.

Nonetheless, the relationship between public spending and poverty has gained sufficient attention in the literature. Demographers are in agreement that expenditure on growth drivers has the capacity to reduce poverty and increase human capabilities which is depicted in Figure 1. Asghar, et al. (2012) posits that economic growth and poverty reduction could occur with government spending on the social sector which would positively affect economic development. Also, according to Fan, Hazell, and Thorat (2000) expenditures on roads, research, and development have the largest impacts on poverty reduction in their study using India. Howbeit results from Gomanee et al. (2005) show the need for new strategies in combating poverty rates, because spending on social services is not as effective as it should be in poverty reduction. This has generated a lot of debate on how effective, the targeting mechanism of government of Nigeria is.

2.1. Federal Government Expenditure on Health in Nigeria

Public expenditure on health has not followed a definitive pattern between 1999 and 2012. The percentage increased from 1.7 in 1999 to 2.7 per cent in 2000, 4.4 per cent in 2001 and 6.2 per cent in 2002 respectively. In 2003, the share reduced to 3.2 percent. Though, health expenditure was 4.2 percent in 2004 and declined slightly to 4.1 percent in 2005. In 2006, the percentage increased to 5.7 percent. Between 2008 and 2010, it declined consistently with 3.7 percent in 2008, and 3.1 percent in 2009 and 2010, respectively. The percentage, however, climbed to 5.8 percent in 2011 and decreased slightly to 5.6 per cent in 2012.

Sources: NBS, CBN (Statistical Bulletin) and Federal Ministry of Finance, 2004, 2008, 2011.

Comparatively, data from selected countries in 2009, shows Haiti as 29.8 percent, Rwanda 27.3 percent, Nauru 25.0 percent, Norway 17.9 percent, Australia 17.2 percent, United Kingdom 16.5 percent, Gabon 13.9 percent, Cameroon 8.6 percent, Niger 10.6 percent and Ghana 6.8 percent (WHO, 2009). The statistics of other countries implies that Nigeria's health spending is weak and needs to be strengthened. Health care indicators also show that public spending on health is a source of concern in Nigeria. The WHO recommends the population to doctor ratio standard at 600: 1. In Nigeria, ratio of population to doctor which stood at 4,529:1 in 2000 further decreased to 5,075:1 in 2007. Between 2009 and 2010 it increased paltry to 3,967:1 and the negative trend is still unbaiting. Available data suggests an annual increase in the number of persons per physicians implying declined access of citizens to the services of physicians. Furthermore, the annual increase in the population to nurse ratio is also worrisome. This indicates reduced access of the citizens to the services of nurses. For example, the ratio stood at 920:1 in 2000 and increased negatively to 1,405:1 in 2007 and has remained high since then. The analysis suggests a higher growth rate of population than the number of nurses. In-addition, most citizens are not aware of the available services and their constitutional rights in relation to the health care.

3. DATA AND METHODS

Most analysis of benefit incidence are derived from the pioneered works of Meerman (1979) and Selowsky (1979) which provides estimates of the distribution of public expenditures. Benefit Incidence Analysis (BIA) normally reveals who is benefiting from public services, and describes the welfare impact on different groups or individual households of government spending. This is achieved by combining information about unit costs of providing those services. In this case, this was obtained from ministries of health as well as private service-providers with information on the use of these services, which was obtained from the households - the 2010 Nigerian Living Standard Survey report (NLSS). Thus, the method could be said to be a measure of how pro-poor government fiscal programme is.

For example, spending on (health), can be formally written as:

$$X_j = \sum_{i=1}^3 E_{ij} \frac{S_i}{E_i} = \sum_{i=1}^3 \frac{E_{ij}}{E_i} S_i \quad (1)$$

As cited in Amakom (2012) where X_j is the amount of the social service (health) subsidy that benefits group j (j is the economic group and for the purpose of this paper, all households have been grouped into 5 quintiles representing their economic status - from the lowest income to the highest income group). S and E refer respectively to the government social sector (health) subsidy and the number that is expected to benefit from the (the number of people that uses the health facility for the health sector), and the subscript i denotes the level of social service (health in Nigeria - healthcare in both private and public are categorized into primary, secondary and tertiary hence $i = 1$ to 3). The benefit incidence of total health imputed to group j is given by the number of primary access from the group (E_{pj}) multiplied by the unit cost of a primary health facility added to the number of secondary

access multiplied by the secondary unit cost of secondary health, plus the number of tertiary access multiplied by the unit cost of tertiary health.

The benefit incidence of total health imputed according to Amakom (2012) to group j is given by the number of users of primary healthcare from the group (E_{pj}) multiplied by the unit cost of providing primary health care and added to the number of users of secondary healthcare which is multiplied by the unit cost of providing secondary healthcare, plus the number of users of tertiary healthcare multiplied by the unit cost of providing tertiary healthcare.

The share of total health spending imputed to group (X_j) is then given by:

$$X_j = \sum_{i=1}^3 \frac{E_{ij}}{E_i} \left(\frac{S_i}{S} \right) = \sum_{i=1}^3 e_{ij} s_i \quad (2)$$

Equation (2) above depends on two major determinants:

1. The e_{ij} 's which are the shares of the group in total service use (number that uses a health facility for health sector) reflect household behaviour.
2. The s_i which is the shares of public spending across the different types of service, reflect government behaviour.

This paper followed a variant procedure, where behavioural information does not determine the monetary valuation of the benefits an individual receives from using public services, rather same monetary value of benefits are assigned to all those who used the services, which is the value of the unit cost of providing the service. The paper is focused on the distribution of beneficiaries from services rather than measuring the exact value to recipients of government-sponsored services (Heltberg, Simler and Tarp 2003). This is the marginal odds of benefits that would accrue to a group for every subsidy or expenditure by government. Given the poor quality of data on public expenditure as well as budget estimates at highly aggregated level, the binary approach proposed by Sahn and Younger (1998) is introduced in our analysis. This bypasses the need for estimating the unit subsidy (S/S_i), which then disappears in equations (1) and (2). Focus is made on only whether a service is used or not with users of public services counted and given the benefit of one, while non-users get zero. Secondly, the above assessment of how the health budget is distributed across the population is based on the observed use of government funded health facilities. This is called current accounting. Thus, it may not give an accurate notion of how changes in the health budget will be distributed across the quintiles.

However, Ajwad and Wodon (2001) and Lanjouw and Ravallion (1999) proposed methodologies that use a single cross-section of data to identify the distribution of increases, at the margin, in access rates to public services. Both studies assumed that the distribution of new access in lagging regions will follow the pattern observed in regions where access rates are higher and used the variation in access rates across regions in a country to capture the expected evolution of access over time. However, the techniques by Ajwad and Wodon (2001) and Lanjouw and Ravallion (1999) differ in the method used for ranking individuals. Furthermore, Lanjouw and Ravallion classify individuals as poor or rich according to their rank in the national distribution of income while Ajwad and Wodon classify individuals

according to their rank in the local distribution of income. This presupposes two differences between the works of Ajwad and Wodon (2000) and Lanjouw and Ravallion (1999). They are as follows:

1. The first concerns the manner in which the endogeneity bias in the estimation of the marginal benefit incidence analysis is handled. Both papers regressed access rate in a given quintile against the mean access rate. The mean access rate, however, includes information from the access rates in each quintile. To purge the mean from this endogeneity, Ajwad and Wodon use the leave-out mean as their right-hand side variable. That is, the access rate in any given quintile is regressed against the average of the access rates across all quintiles, except for the quintile for which the regression is performed. Lanjouw and Ravallion, on the other hand, use an instrumental technique, whereby the actual mean is instrumented by the leave-out mean.
2. The second is that Ajwad and Wodon constrain the estimates of the marginal benefit incidence analysis to sum to one, and show that without such a constraint, the estimates will be biased downward, while Lanjouw and Ravallion does not.

Furthermore, Lanjouw and Ravallion provide the following econometric method which has been used in a few studies (Ajwad and Wodon, 2001; Kamgnia et al., 2008; Demery and Gaddis, 2009), given as:

$$\rho_{i,j,q} = \alpha_q + \beta \rho_k + \mu_q \quad (3)$$

Where i index a small geographical unit, k indexes a larger one, and q indexes the welfare quantile. The left-hand variable is the program participation rate for the division and quantile. The regressor is the program participation rate for the region in which the division is located. q , then is the marginal effect of an increase in the program participation rates of people in a given region and quantile. According to Lanjouw and Ravallion (1999), the average participation rate is defined as the proportion of the population of a particular quintile that participates in a government sponsored program. The regressor is run separately for each quantile. In addition, because ijk is included in k , there is an upward bias in the estimation. As mentioned earlier, Lanjouw and Ravallion resolved this problem by instrumenting k with the left-out mean. The intuition behind the regression is that by observing variations in participation, it is possible to understand how increased coverage affects the participation of different population groups. If q is greater than one, it indicates that a general expansion in coverage is correlated with a disproportionately large increase in participation for that division and quantile. An important assumption in our model is that across locations the same political process determines the correlation between program discretion and incidence. Also, the margin that this model estimates is the incidence of an increase in program participation.

3.1. Justification of Method (Previous Studies)

According to Demery et al. (1995); Castro-Leal et al. (1996); Sahn and Younger (2000); Van de Walle (2003), the World Bank have conducted studies in low and middle income

countries using the method. O'Donnell et al. (2007) in their analysis used the technique and justified it because of its application in recent years. Also, Reinikka (2002) posits that employing BIA is most deserving because of evidence of limited impact of public spending on growth and human development outcomes which is the case in Nigeria. Nonetheless, who benefits from government spending is same as judging public policy efficiency in addressing issues on poverty and inequality. Younger (2002) considered a variety of options for analyzing the marginal benefit incidence of policy change and argued that despite the reality that each approach measures, marginal incidence, they neither in reality measure the same thing nor propose to do. Empirically, the accuracy of the approaches varies considerably with those relying on the dissimilarity data or aggregations of household into groups yielding normal errors that are fairly large relative to the expected shares.

Demery (1995) and the World Bank (1995a) used the Benefit Incidence Analysis (BIA) methodology for Ghana, Bulgaria and Vietnam and their results showed that women gained more in terms of an in-kind transfer of about 4,321 cedis per-capita as against 3,576 cedis per-capita in Ghana. Also, their results showed that the Bulgarian Turks¹ were the most disadvantaged when compared to the Gypsies. On the average, the Turks and Gypsies represent Thirteen percent of the population, but they received only six per cent of health subsidy. In Vietnam, the results showed that the mean subsidy for hospital inpatient and outpatient care was used for the benefit incidence estimates. Furthermore, Ghana results showed that a major source of inequality in the benefit incidence of health spending in Ghana was the gender dimension. Females benefited more than males in terms of health subsidy and there was a wide disparity in racial access to health. However, targeting health services to the poor have an ethnic undertone in Bulgaria, but there was no conclusion for Vietnam in the study.

Castro-Leal et al. (1999) examined health and education spending using comparative benefit incidence analysis. He finds that on average, the amount of overall government health spending going to the top twenty 20 per cent of the population was about two and a half times the amount benefiting the bottom 20 per cent. The highest 20 per cent of the population received more financial gains than the lowest 20 per cent in five of the seven countries; overall, the richest 20 per cent gained about one and a half times from primary care expenditure as much as the poorest 20 per cent. The study concluded that public spending in all the countries was found to be reverting.

Ajay et al. (2000) in their study employs BIA in appraising the distributional impacts of health spending in India and its principal states and uncovers that public health spending benefited the richer than the deprived. The financial gains from primary and outpatient service were less unequally allocated than those from hospital care. Overall, the pro-rich favoritism was larger in rural than in urban areas and greatly in poor than in richer states. Also, the gains connected with hospital services were less improving than other health facilities according to findings. Generally, the survey concluded that social services were poorly targeted while concentration curves are helpful method to sum up details on the gains of public spending, statistical examination of disparities in curves is imperative.

¹ The Turks and Gypsy are the two minority groups in Bulgaria comprising 13% of the total population, 25% of the poorest quintile and very few are found among the better off (only about 3% in the richest quintile).

Heltberg et al. (2001) and (2003) estimated the spread of government expenditure by socio-economic status in Mozambique. They used the non-behavioral method and found that outcomes from the method is that post-primary education crosses the Lorenz curve at 0.1 on the horizontal axis, and lies below the Lorenz curve for the rest of the allocation. Results indicate that the poorest 50 per cent of school children constitute about 50 per cent of students enrolled in lower primary and 32 per cent of students in upper primary. The poorest half of the sample accounted for about 19 per cent and 11 percent of students in post-primary education and intermediate post-primary education respectively. Their results confirmed earlier positions that services in Mozambique² were more equal than most African countries and a progressive distribution for services in health and public infrastructure is in place. Amakom (2012 and 2011) in separate studies for Nigeria using the Nigerian Living Standard Survey of 2004 evaluates public spending efforts in reducing inequality and poverty at all levels of both education and health sectors using the benefit incidence analysis (BIA). Results suggest that primary education and primary healthcare were more pro-poor than tertiary education and tertiary healthcare in absolute terms. Furthermore, secondary education and secondary healthcare showed varied results while findings suggest state, region, location and gender partiality influence benefits from government expenditure for education and health services. In conclusion, the study posits that income redistribution may be achieved through subsidies, and not through direct consumption transfers.

However, Soares et al. (2006) developed an approach that separated out the income of different cash transfers. Evaluating the incidence of the programmes using concentration curves indexes and decomposing the Gini indexes. Soares et al. (2006) found that the old age pension and disability grant programmes were targeted properly. Study indicates that the analysis of distributive effects of these programmes contributes to the correction of existing deficiencies; thus implying that the planning of future expansion of the programmes in eradicating poverty and inequality could be achieved within a reasonable time frame. Furthermore, Soares (2006) in his health and the evolution of welfare across Brazilian municipalities study compensates differentials method in estimating the value of the observed reductions in mortality. The results suggest that benefits in life expectancy are responsible for about 28 per cent of the improvement in welfare with a welfare value equivalent to 39 per cent of the growth in income per capita. The study concluded that initial income disparity across Brazilian municipalities was very high and life expectancy benefits were more or less uniform.

² Except for Upper Secondary and University Education.

4.1. Discussion

A major measurement of success, progress of poverty reduction has been the trend and allocation of resources. This propelled structural adjustment programmes across many countries and according to Geoff et al. (2009), many recorded positive growth rates. It should be noted that in the 1970s, 1980s and 1990s the focus was on growing economies and incomes. This strategy took a new dimension in the 2000s. Thus, financing of social sectors was seen as a strategy to propel growth. In addition, during 1990s, a dominant view in development literature was that growth is the end game for every poverty reduction strategy. Several studies indicated that countries with fast and high growths made progress on poverty reduction via health and education (World Bank, 2000; Dollar and Kraay 2000). Ravallion and Datt (1996) and Mellor (1999) modified this view and argued that it is not growth per se, but the structure of benefits across population groups is fundamental in poverty reduction.

Table 2 above gives the estimated benefits and marginal odds of using public primary health services obtained by regressing participation rates of each quintile across average participation rate. The estimated numbers in the table can be interpreted as the gain in subsidy incidence per capita for each quintile from a one Naira increase in aggregate spending on primary healthcare. A cursory look at the table 2 indicates a pro-poor target for only three states (Anambra, Ebonyi and Enugu) out of five SE States regarding primary healthcare. Quintiles (1, 2 and 3) for the states showed that more benefits from the allocations were received by the vulnerable group. They received a benefit of more than N1 expenditure from government. This is in-tune with MDG Goal 4: Reducing Child Mortality and MDG Goal 5: Improving Maternal Health. However, this supposed improvement would not show an improved average because the other states are still far off from the expected mark. The other three states to a great extent subsidized the rich in the society, which obviously would lead to further poverty and weakness in overall health structure. In- as much as Ebonyi State showed some targeting, resources devoted to the rich was on the high side. These resources could have been re-channeled towards the weak and vulnerable in the society. Out of a 100 per cent scale, Anambra and Enugu states subsidized Quintile 5 with 3.9 per cent and 5.9 percent respectively while Ebonyi, Imo and Abia states gave 16.4 per cent, 16.7 per cent and 18.4 per cent respectively to the same group. The scenario suggests that the scourge of poverty at the minimum would still be felt by the people who do not have access to primary health care.

Health data from developing countries invariably indicates higher-than-average instances of disease, premature mortality, maternal mortality, or HIV/AIDS infection rates. A preliminary conclusion would be that poverty is increasing the vulnerability of the poor to health-related problems in these countries, as well as exacerbating ill-health and whether poverty in itself is proving an impediment to the capacity of the poor to seek adequate health care when sick. A comparative study of Demographic and Health Surveys in over 25 countries suggests that the health status of children is closely linked to poverty, thus suggesting the need for a proper targeting of resources to the vulnerable to abate this scenario.

Table 3 and 4 above gives the estimated benefits and marginal odds of using public secondary health services obtained by regressing participation rates of each quintile across average participation rate. The estimated numbers in the table can be interpreted as the gain in subsidy incidence per capita for each quintile from a one Naira increase in aggregate spending on secondary and tertiary healthcare. At the secondary healthcare level, three states from the

South East showed an incidence of more than 1 which is good for population group in quintile 1. However, population group under quintile 4 and quintile 5 still had the largest benefits from the discretionary spending by the respective state governments. Results from Table 3 shows that targeting for quintiles 1, 2 and 3 were better than quintiles 4 and 5. They collected over 60%. Nonetheless, quintile 5 collected about 20% of the resources which is not pro-poor. The same trajectory was observed at the tertiary level. Table 4 indicates high significant values for quintile 4 and 5 across the five (5) states. These group, benefited about 50% of the public resources. However, this pattern is believed to be occurring across all the states in Nigeria. The structure suggests a total exclusion of the poor from development decisions. There was poor targeting for quintile 1 and quintile 2. The vulnerable group (quintile 1 and 2) in this case, did not benefit at this level. They only had about 155 of total resources. This situation is an aberration of development. Furthermore, tertiary health care is designed to benefit the poor who cannot afford the cost of overseas specialist treatment, but the reverse is the case here. The very rich and the rich across the five eastern states of Nigeria benefited more than the poor. This situation can only support the widening inequality in the system. Our results are supported by Foster et al. (2002). Key findings from other work in five Sub-Saharan African countries, specifically Ghana, Malawi, Mozambique, Tanzania and Uganda, indicated the existing relationships between poverty reduction approach and public social spending management in each country. They established that the efficiency and effectiveness of public spending were very low and benefited largely the wealthy.

Furthermore, the work of Sahn and Younger (1999) using a benefit incidence approach focused on Ghana, Cote d'Ivoire, Guinea, Madagascar, South Africa, Uganda, Tanzania, and Mauritania, concluded that social services were poorly targeted in these countries. This confirms the ambivalence observed in Nigeria. Evidence in Nigeria from different studies (Ichoku 2008) indicates that in the health sector, the nature of the tertiary health-care which includes tertiary facilities like teaching hospitals, medical colleges and specialist hospitals are in shambles and hence has been a boost for health tourism in favour of other countries with better health facilities. Despite this trend, the upper class are still being subsidized by government going by our results. In the health sector, for example, poorer households across some states are already incurring catastrophic expenditure as they spend 40% or more of their discretionary (non-food) on health-care. Amakom and Ezenekwe (2012) analyzed whether there is a positive association between a household's poverty shortfall and its health out-of-pocket budget share from two standpoints. Their study found that high out of pocket (OOP) in healthcare has succeeded in changing the poverty situation (pushing households below poverty line) even households who were originally on or above the poverty line including some of the households that were originally in the 4th and 5th quintiles. Statistical data from WDI seem to concur with the above findings, as it suggests that out-of-pocket health expenditure (per cent of private expenditure on health) was 95.34 per cent in 2010 while the Nigerian Medical Association (NMA) in 2012 opined that over 5,000 Nigerians travel to India and other countries monthly for medical treatment implying that the country spends between \$1bn and \$2bn in medical tourism annually. A total mis-alignment is observed with the health expenditure in the SE region of Nigeria. Households that need the services don't get it, whereas richer individuals are greatly subsidized.

CONCLUSION AND RECOMMENDATION

Two recent surveys in Nigeria have shown a low index for health. Firstly, the Nigerian Living Standard Survey (NLSS) of 2004 estimated on the average, an annual per capita for health (out of pocket expenditure) to be equivalent to twenty-two dollars (US\$ 22). The 2004 Survey collected data on household health expenditures from a representative sample of 19,159 households. The estimate from these data of average annual per capita out-of-pocket spending on health is Naira 2,999, equivalent to around US\$ 22. Out-of-pocket health expenditure by households constituted over 8 percent and was mostly on out-patient care, transportation to facilities and medication, showing that government expenditure on health sector is not effective. This represents one of the largest shares of health expenditure out of total family spending for developing countries. Secondly, the 2009/2010³ survey which is the follow-up to the 2004 survey showed similar trends. The total health expenditure share of Household for 2009/10 decreased to 7.51 from 7.78 in 2004. Statistics suggests that fewer households visited a health provider in comparison with the 2004 survey results, indicating a lack of confidence on the services provided by the government. Also, the 2009/2010 survey results show that poverty and inequality have been on the increase since the last survey of 2004. Unfortunately, available records suggest, that this trend is still unabated at the moment and indicative that health services payment in Nigeria is still from out-of-pocket expenses. This scenario equally shows that the middle and upper class that benefit from local health facilities are still not satisfied with the health system. This has inadvertently, skewed health benefits to urban areas and for the middle and upper class mostly.

Lack of access and uneven benefits to healthcare services makes the poor vulnerable. Furthermore, the lack of healthcare access contributes to marginalization of the poor and widening inequality. Focusing on re-balancing of expenditure benefits as well as raising health standards by the authorities in Nigeria could enhance empowerment, which represents the expansion of assets and capabilities which will allow households in Quintiles 1 and 2 participate fully; negotiate and hold accountable institutions that affect their lives. Access and benefits to healthcare services not only imparts specific knowledge and develops general reasoning skills, but leads to changes in beliefs and values, as well as attitudes toward work and society. For the Government of Nigeria to meet the challenge of initiating an inclusive rapid growth and social transformation, spending options must be derived from evidence based analysis and evaluation of “who gets what, when and how”.

Summarily, poverty and inequality reduction strategies in Nigeria, therefore, have to incorporate effective benefit distributive features and high level of inclusiveness. There are glaring indications that in the SE region of Nigeria, those living in poverty do not enjoy the same levels of care and treatment as other people on a higher income level. Some may not access any health care at all because of poor targeting of resources by the government as a result of absence of a counter-factual framework by the government. This means that poor people are less able to enjoy protection against ill-health that is beneficial for higher income

³ The 2009/2010 Survey is an enlarged survey compared to that of 2004. The questionnaire included Demographics; Health; and Fertility behaviour, Education and Skills/Training; Employment and Time-use; Housing and Housing Condition; Social Capital, Agriculture; Social Capital, Agriculture; Household Income, consumption and Expenditure.

groups and consequently, most children of poor households may not benefit from immunization programmes by the government.

In this chapter, we analyzed which demographic quintile benefits from discretionary government spending. However, the methodological and framework in this chapter, does not address the policies that might bring about program expansion for health. Rather, it makes a more general appeal to the political economy behind the policies to argue that, whatever policies are used, the outcome must respect the political constraints implied by each group's cost, benefits, and political power.

From the foregoing, a maximum impact in targeting poverty in Nigeria would be achieved if all the states in Nigeria focus on social sector resources exclusively on the households within Quintiles 1(very poor) and 2 (poor) across the country. This would support poverty reduction via productivity increase of able-bodied men and women. Furthermore, households and communities should be enlightened and their consciousness increased in understanding how best to access health care in their various jurisdictions for maximum positive impact on their socioeconomic status. We, therefore, recommend the subsidization of health services for the poor by the use of local government financing, and similar tools in the engagement of communities in their health care programmes. Effective inclusion and targeting of the poor and less privileged in sustaining societal growth and economic progress may be a potent strategy for curtailing poverty and inequality. Health care services are a prominent social good that is very much needed by the citizenry; hence efforts at providing these services should be a national priority. Government should invest more on social services and enhance access to primary health care with a focus on outcomes and not outputs.

BIOGRAPHICAL SKETCHES

Kanayo Ogujiuba

Affiliation: Statistics and Population Studies, University of the Western Cape

Education: PhD Statistics; PhD Economics

Address: Bellville 7530, Cape Town, South Africa

Research and Professional Experience: Ogujiuba Kanayo is affiliated with the Statistics and Population Studies Department, University of the Western Cape. His research interests include technical demography, development and public policy. He has published several articles in accredited Journals and is a member of numerous research and management development networks.

Nancy Stiegler

Affiliation: Statistics and Population Studies, University of the Western Cape

Education: PhD Demography

Address: Bellville 7530, Cape Town, South Africa

Research and Professional Experience: *Nancy Stiegler* is the Chairperson of the Statistics and Population Studies Department. She teaches demographic analysis to postgraduate and undergraduate students, and conducts research in the fields of reproductive health, female rights and census issues.

Chapter 383

OVERVIEW OF U.S. DOMESTIC RESPONSE TO CORONAVIRUS DISEASE 2019 (COVID-19)*

***Sarah A. Lister, Kavya Sekar, Agata Dabrowska,
Frank Gottron, Audrey Singer and Amanda K. Sarata***

BACKGROUND

On December 31, 2019, the World Health Organization (WHO) was informed of a cluster of pneumonia cases in Wuhan City, Hubei Province of China. Illnesses have since been linked to a disease caused by a previously unidentified strain of coronavirus, designated Coronavirus Disease 2019, or COVID-19. The disease has spread to several other countries, including the United States. As of March 2, 2020, tens of thousands of people have been infected and over 2,500 have died. Both WHO and the U.S. Centers for Disease Control and Prevention (CDC) post frequent updates on the outbreak.¹

On January 30, 2020, the Emergency Committee convened by the WHO Director-General declared the COVID-19 outbreak to be a Public Health Emergency of International Concern (PHEIC).² The next day, on January 31, 2020, U.S. Department of Health and Human Services (HHS) Secretary Alex Azar declared the outbreak to be a Public Health

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. R46219, dated March 2, 2020.

Emergency pursuant to Public Health Service Act (PHSA) Section 319, retroactively dated to January 27, 2020.³

Despite containment efforts in China, the United States, and elsewhere, by late February there were indications that the COVID-19 outbreak may have entered a new phase, with community spread occurring or suspected in several countries other than China, and in at least two U.S. states. According to federal health officials, the COVID-19 outbreak currently meets two of three criteria needed to be considered a pandemic, namely that the disease has caused illness, including illness resulting in death, and that there is sustained person-to-person spread. They note that as community spread is detected in more and more countries, “the world moves closer toward meeting the third criteria, worldwide spread of the new virus.”⁴ In addition, they say

...we should be prepared for COVID-19 to gain a foothold throughout the world, including in the United States. Community spread in the United States could require a shift from containment to mitigation strategies such as social distancing in order to reduce transmission. Such strategies could include isolating ill persons (including voluntary isolation at home), school closures, and telecommuting where possible.⁵

This report discusses selected actions taken by the U.S. federal government to quell the introduction and spread of COVID-19 in the United States. The President, the HHS Secretary, and other federal officials have taken several specific actions to address this threat. While some of these actions are based in generally applicable authorities, others may be contingent upon the Secretary or another federal official making a determination or declaration, specific to that action, regarding the existence of a public health emergency or threat. Key actions and their legal basis are discussed in this report.

A Snapshot of the Domestic Response to COVID-19, as of March 3, 2020 Note: All dates below are in 2020.

International

<https://www.who.int/emergencies/diseases/novel-coronavirus-2019>

- WHO declared the COVID-19 outbreak to be a PHEIC on January 30.
- WHO announced the official name for the disease, COVID-19 on February 11.
- WHO raised its global risk assessment for the outbreak to “very high,” its highest risk level, on February 28.
- Globally, almost 90,000 cases have been confirmed, including almost 3,000 deaths. Cases have been reported in 58 countries.

United States

- A Public Health Emergency is in effect under Section 319 of the Public Health Service Act.
- President Donald Trump has announced the formation of the President’s Coronavirus Task Force, and appointed Vice President Mike Pence as the coordinator for the U.S. COVID-19 response.
- For response efforts, the HHS Secretary has allowed for the allotment of \$105 million in funding from the Infectious Diseases Rapid Response Reserve Fund, and also requested an appropriations transfer of up to \$136 million. The Administration has submitted to Congress a request for \$1.25 billion in emergency supplemental appropriations, and asked for authority to re-allocate another \$1.25 billion. Congress has begun discussions of supplemental funding, likely in amounts to exceed the Administration request.
- CDC has developed a diagnostic test for the virus and distributed it to certain public health laboratories at the state and local level, pursuant to an Emergency Use Authorization (EUA) issued by FDA on February 4. Problems with test performance have limited access to testing at a local level.
- FDA issued guidance on February 29 to authorize certain certified labs, including non-government hospital labs, to use their own COVID-19 laboratory-developed tests for clinical diagnosis before EUA is granted.
- Travel restrictions and quarantine requirements are in effect for certain travelers who have been in mainland China or the Islamic Republic of Iran within 14 days prior to arrival, pursuant to Proclamations issued by President Trump.
- U.S. Department of State and other agencies have ordered or facilitated the repatriation of certain federal employees from China.
- Travel warnings by CDC and State Department are in effect for several countries including China, South Korea, Italy, and Iran.
- CDC has issued guidance for the general public, health care providers, health departments, pregnant women and children, travelers, and others.
- CDC reports 43 U.S. cases identified through public health surveillance, and an additional 48 cases among persons repatriated to the United States. CDC reported the first instance of possible community spread on February 26.
- Outbreaks have been reported in California, Oregon, and Washington State. Nine deaths have been reported in Washington State, four of them associated with a nursing home outbreak.

EPIDEMIOLOGY OF COVID-19

Coronaviruses (see Figure 1) are common respiratory pathogens, usually causing mild illnesses such as the common cold; however, several strains that cause serious illness have emerged in recent years. COVID-19 is the third serious outbreak caused by a novel coronavirus in modern times, following severe acute respiratory syndrome (SARS) in 2002 and Middle East Respiratory Syndrome (MERS) in 2012.⁶ The global health community is closely monitoring COVID-19 because of the severity of symptoms (including death) among those infected and the speed of its spread worldwide. Experts do not know the origin of COVID-19, though genetic analysis and other features suggest an animal source.⁷

Health officials and researchers are still learning about COVID-19 (see text box on “What We Know About COVID-19”). COVID-19 is a respiratory infection characterized by a fever, cough, and sometimes breathing difficulty—a suite of symptoms that is common during influenza season.⁸ Although initial COVID-19 cases likely resulted from animal

Ian Lipkin, “The Proximal Origin of SARS-CoV-2,” *Virological*, pre-print, February 2020, virological.org/t/the-proximal-origin-of-sars-cov-2/398; and CDC, “Coronavirus Disease 2019 (COVID-19) Situation Summary,” updated February 16, 2020, <https://www.cdc.gov/coronavirus/COVID-19/summary.html>.

⁸ CDC, “Symptoms—Coronavirus Disease 2019,” accessed February 18, 2020, <https://www.cdc.gov/coronavirus/COVID-19/about/symptoms.html>.

contact, Chinese officials confirmed person-to-person transmission on January 21, 2020.⁹ While health officials and researchers are still learning about the disease, CDC has concluded the following about COVID19:

- **Routes of transmission.** Based on how similar viruses spread, the virus is thought to spread via respiratory droplets and between people who are in close contact with one another (within about six feet). The virus may also spread via infected surfaces or objects, but according to CDC, this is not thought to be a primary means of transmission.¹⁰
- **Incubation period.** Health officials and researchers are still determining the virus's incubation period, or time between infection and onset of symptoms.¹¹ CDC is using 14 days as the outer bound for the incubation period, meaning that the agency expects someone who has been infected to show symptoms at some point during those 14 days.¹²
- **Transmission from asymptomatic patients.** CDC has confirmed that some transmission may occur before people show symptoms, based on a few reports and general characteristics of respiratory viruses.¹³ However, the agency, WHO, and other health experts agree that asymptomatic spread is unlikely to be a main driver of the outbreak.¹⁴

At this time, no specific treatment or preventive vaccine exists for COVID-19. Care for patients is supportive: maintaining hydration, preventing secondary infections, and providing respiratory support, such as use of a ventilator, if needed.¹⁵

What We Know About COVID-19

As the outbreak has progressed, researchers and health officials have been learning about the disease and its epidemiology. Initially, data and reporting from China, the epicenter from the outbreak, was limited and uncertain. With the recent WHO mission to China and more data coming from other countries, experts have a better understanding of the clinical features of the disease and how it spreads. Some of the key findings include:

- Data from China suggests that serious illness occurs in about 16% of people.
- Older people and people with underlying health conditions, like heart disease, lung disease and diabetes, for example, were about twice as likely to develop serious outcomes versus otherwise younger, healthier people.
- Disease in children appears to be relatively rare and mild with approximately 2.4% of the total reported cases reported amongst individuals aged under 19 years.

Experts are still understanding the exact fatality rate and attack rate (how easily the virus transmits), among other epidemiological characteristics. There is still uncertainty if the full spectrum of disease (including all mild cases) has been captured in the data from other countries, which affects our understanding of severity and transmission. Regardless, estimates suggest that the disease has a higher case fatality rate than the annual flu. Given the uncertainty, CRS presents conclusions that have been made by CDC and/or WHO.

See WHO, “Report of the WHO-China Joint Mission on Coronavirus Disease (COVID-19),” February 16-24, 2020, <https://www.who.int/docs/default-source/coronaviruse/who-china-joint-mission-on-covid-19-final-report.pdf>.

DOMESTIC RESPONSE

The nation has both planning and real-world experience with pandemic infectious diseases, most notably the influenza pandemic of 2009.¹⁶ Although COVID-19 is from a different family of viruses, its similarity to influenza—the route of spread, respiratory system effects, and the possible role of antiviral drugs and vaccines, for example—allow the body of influenza experience and plans across government and the private sector to be applied to the COVID-19 response, with modest adjustments.¹⁷

Domestic communicable disease control involves collaboration among federal agencies, state health departments, and international partners. Many public health authorities are based in state law, such as authority to compel isolation (for sick patients), quarantine (for healthy exposed persons), and disease reporting.¹⁸ The HHS Secretary and, by delegation, CDC have broad authority to assist in the control of communicable diseases through international cooperation, federal-state cooperation, and public health emergency response activities.¹⁹ CDC (by delegation) also has explicit authority to detain, examine, and release persons arriving into the United States, and traveling between states, who are suspected of having a communicable disease.²⁰ Other authorities, such as those in the Immigration and Nationality Act of 1952 (INA, P.L. 82-414), allow for other actions relevant to communicable disease control, such as travel restrictions.²¹

²¹ 8 U.S.C. Chapter 12.

The use of federal and state disease control authorities and other key actions taken in response to the COVID-19 outbreak are discussed below. These activities of federal agencies in collaboration with state and local governments include, among others (1) investigation of COVID-19 cases and infection control measures in the community, (2) travel restrictions and/or quarantine requirements on certain travelers who have recently visited China, (3) medical countermeasure development, and (4) health system preparedness. Federal agencies involved include several HHS agencies, such as CDC, the Assistant Secretary for Preparedness and Response (ASPR), the National Institutes of Health (NIH), and the U.S. Food and Drug Administration (FDA), in collaboration with other agencies such as the U.S. Department of State and the Department of Homeland Security (DHS).

Investigation and Control of COVID-19 Cases in the Community

To curb the spread of COVID-19 cases in the community, state, tribal, local, and territorial health departments, with support from CDC, work to identify cases, investigate the possible spread of disease, and take infection control measures.

Case identification begins with diagnostic testing for COVID-19. As of February 27, CDC guidance urges clinicians to consider a patient's travel and/or contact history, as well as symptoms when deciding to test for COVID-19. CDC recommends COVID-19 testing for patients without known travel and/or contact history if clinical features include, "fever with severe acute lower respiratory illness ... requiring hospitalization and without alternative explanatory diagnosis (e.g., influenza)." ²² (See the next section, "The Role of Laboratories in Testing" for more information about the CDC-developed test.) Health care providers are urged to report possible cases to jurisdictional health departments, which then report to CDC. ²³

Once a patient is reported and in the process of having specimens tested, he or she is considered a *patient under investigation* (PUI) for COVID-19. CDC has developed guidelines for isolation and other precautions for PUIs (including potential PUIs) or those receiving supportive care for COVID-19 infection in health care settings. ²⁴ A key goal of the guidelines is the prevention of disease transmission to health care workers, who may be exposed through high-risk procedures, such as maintaining an ill patient on a ventilator. ²⁵

Disease investigation for confirmed cases involves *contact tracing*—identifying and evaluating individuals who had contact with the patient to determine if transmission has occurred. These investigations are generally conducted by jurisdictional health officials, often with support and technical assistance from CDC. ²⁶ CDC has reported community spread in

²² CDC, "Evaluating and Reporting Persons under Investigation (PUI)," updated February 27, 2020.

three states during the week of February 23, including a potential outbreak in a long-term care facility.²⁷

Jurisdictional health departments may take actions at a local level to control the spread of COVID-19. For example, the government of Washington State declared a state of emergency on February 29.²⁸ In addition, schools in the states of Washington and Oregon have had temporary closures due to presumptive positive COVID-19 cases.²⁹ If and when outbreaks continue, jurisdictions may consider actions such as cancellation of events and encouraging telecommuting for workers. Such actions would be based in state and local level authorities.

As of February 29, 2020, CDC reported that it had “deployed multidisciplinary teams to support health departments with clinical management, contact tracing, and communications.”³⁰ In addition, the Public Health Emergency declaration by Secretary Azar, pursuant to PHS Act Section 319, gives jurisdictional health departments more flexibility to reassign personnel to respond to COVID-19.

The Role of Laboratories in Testing

Every state, territory, and the District of Columbia has a central public health laboratory. These laboratories play many roles, including specialized testing for the detection and identification of infectious disease.³¹ Depending on the structure of their respective public health systems, states may also operate local public health laboratories.³² Health care facilities and businesses also separately operate laboratories outside of the public health laboratory system and are regulated by the FDA.

Typically, in emergency situations involving novel pathogens, diagnostic testing is initially centralized under CDC because CDC has the equipment, trained personnel, and facilities to provide the containment necessary to safely carry out the testing. Once a CDC-developed test is ready and meets any related regulatory requirements, the test may be distributed to state and local public health laboratories to expand testing capacity.

Initially, CDC performed all domestic COVID-19 testing, using a diagnostic test it developed, and continues to confirm presumptive positive cases.³³ The CDC test, 2019-nCoV Real-Time RTPCR Diagnostic Panel, is a molecular diagnostic test that requires specialized equipment and laboratory expertise.³⁴ It is intended for use only by laboratories designated by CDC as qualified and certified to perform high-complexity testing under the CLIA (Clinical Laboratory Improvement Amendments of 1988) program, administered by the HHS Centers

for Medicare & Medicaid Services (CMS).³⁵ In the national Laboratory Response Network (LRN) supported by CDC, approximately 130 laboratories, mostly governmental, have the capability to perform specialized testing for high-risk clinical samples, such as those for COVID-2019.³⁶

On February 5, 2020, CDC announced that it would begin distributing test kits to jurisdictional laboratories, following an Emergency Use Authorization from FDA (see the “Medical Countermeasures” section for more details).³⁷ After distribution began, problems with one of the reagents (i.e., test chemicals), later reported to be linked to manufacturing, led to inconclusive test results in many laboratories.³⁸ Performance problems with the CDC test persisted throughout the month of February.

On February 27, 2020, CDC and FDA reported that the problem of inconclusive test results was resolved and that newly manufactured tests were again being distributed to state and local public health laboratories.³⁹ CDC reported that 40 laboratories in 32 states and the District of Columbia had received test kits, with additional kits to be made available to public health laboratories through the International Reagent Resource (IRR), a repository established by CDC.⁴⁰ Domestic laboratories are not charged for reagents or shipping from the IRR.

For more information on U.S. diagnostic testing, see CRS Report R46261, *Development and Regulation of Domestic Diagnostic Testing for Novel Coronavirus (COVID-19): Frequently Asked Questions*, by Amanda K. Sarata.

Travel-Related Policies and Restrictions

Given that initially the spread of COVID-19 cases was linked to travel, particularly to mainland China, several policies have been implemented to curb travel-related cases. These have included CDC and State Department advisories to avoid travel to certain countries, and specific restrictions and quarantine requirements on travelers returning from mainland China or Iran pursuant to presidential proclamations (further explained below). In addition, screening programs have been implemented at U.S. airports and other ports of entry to evaluate the health of returning travelers. As COVID-19 continues to spread globally, screening and entry policies may continue to evolve.

COVID-19 Travel Restrictions and Quarantine Requirements: Legal Basis

The Trump Administration has imposed two types of movement restrictions to prevent the entry and/or spread of COVID-19 in the United States. First, an immigration restriction generally suspends the entry of foreign nationals who have been in mainland China or in the Islamic Republic of Iran (Iran) within the prior 14 days.⁴¹ Second, quarantine requirements have been imposed on persons entering the United States if they have been in mainland China within the prior 14 days.⁴² Persons entering the United States who have been in Iran within the prior 14 days are subject to health monitoring.⁴³

Entry Restriction

President Trump issued a Proclamation on January 31, 2020, that suspends the entry of any foreign national who has been in mainland China within the prior 14 days, subject to some exceptions.⁴⁴ Hong Kong and Macau, both Special Administrative Regions of the People's Republic of China, are explicitly exempted. The China Proclamation directs the U.S. Department of State and the Department of Homeland Security (DHS) to establish procedures for implementing and enforcing the entry restrictions, which by the Proclamation's terms took effect on February 2, 2020. On February 29, 2020, President Trump issued another Proclamation with similar restrictions and exceptions for foreign nationals who had been in Iran within the prior 14 days.⁴⁵ In similar fashion, the Iran Proclamation's terms took effect on March 2, 2020. Both proclamations excepted lawful permanent residents (LPRs), most immediate relatives of U.S. citizens and LPRs, and some other groups such as some airplane and ship crew members.⁴⁶

For statutory authority, the Proclamations rely principally upon Section 212(f) of the Immigration and Nationality Act (INA).⁴⁷ That statute authorizes the President to "suspend the entry of all aliens or any class of aliens" whose entry he "finds ... would be detrimental to the interests of the United States."⁴⁸ The Supreme Court has held that Section 212(f) "exudes deference to the President in every clause" and gives him mostly unfettered discretion to

⁴¹ The travel restrictions for China became effective on February 2, 2020, and for Iran, March 2, 2020. The White House, *Remarks by President Trump, Vice President Pence, and Members of the Coronavirus Task Force in Press Conference*, February 29, 2020, <https://www.whitehouse.gov/briefings-statements/remarks-president-trump-vice-president-pence-members-coronavirus-task-force-press-conference-2/>.

⁴² Although the incubation period for COVID-19 has not yet been established, the U.S. Centers for Disease Control and Prevention (CDC) advises that "[f]or COVID-19, the period of quarantine is 14 days from the last date of exposure because 14 days is the longest incubation period seen for similar coronaviruses." Centers for Disease Control and Prevention, "Coronavirus Disease 2019 (COVID-19)," updated February 15, 2020, <https://www.cdc.gov/coronavirus/2019-ncov/faq.html>.

⁴³ Centers for Disease Control and Prevention, *Travelers from Countries with Widespread Sustained (Ongoing) Transmission Arriving in the United States*, accessed March 4, 2020, <https://www.cdc.gov/coronavirus/2019-ncov/travelers/after-travel-precautions.html>.

⁴⁴ The White House, "Proclamation on Suspension of Entry as Immigrants and Nonimmigrants of Persons Who Pose a Risk of Transmitting 2019 Novel Coronavirus," January 31, 2020, <https://www.whitehouse.gov/presidential-actions/proclamation-suspension-entry-immigrants-nonimmigrants-persons-pose-risk-transmitting-2019-novel-coronavirus/> [hereinafter *China Proclamation*].

⁴⁵ The White House, "Proclamation on Suspension of Entry as Immigrants and Nonimmigrants of Persons Who Pose a Risk of Transmitting 2019 Novel Coronavirus," February 29, 2020, <https://www.whitehouse.gov/presidential-actions/proclamation-suspension-entry-immigrants-nonimmigrants-certain-additional-persons-pose-risk-transmitting-coronavirus/> [hereinafter *Iran Proclamation*].

⁴⁷ 8 U.S.C. §1182(f).

⁴⁸ *Id.*

decide “when to suspend entry,” “whose entry to suspend,” “for how long,” and “on what conditions.”⁴⁹ The Proclamations are in effect until terminated by the President.⁵⁰ The Proclamations also direct the Secretary of Health and Human Services (HHS) to “recommend that the President continue, modify, or terminate this proclamation and any other proclamation suspending or limiting the entry of foreign nationals into the United States as immigrants or nonimmigrants because of the threat posed by the virus.”⁵¹ Such recommendation is required “no more than 15 days after the date of this order and every 15 days thereafter.”⁵²

Although the Supreme Court has affirmed broad presidential discretion in the application of Section 212(f), the travel restriction applied in response to COVID-19 is the first such use of this authority to control the spread of a communicable disease.

Quarantine Requirements

DHS announced quarantine requirements, for arrivals on and after February 2, 2020 from China, and for arrivals from Iran, as of March 2, 2020.⁵³ Travelers who arrive in the United States within 14 days after having been in mainland China, are to be screened at one of 11 designated airports (see text box). Such persons may also be subject to mandatory quarantine, pursuant to the standing quarantine authorities of the HHS Secretary under Section 361 of the Public Health Service Act (PHSA).⁵⁴ These authorities are generally implemented by the CDC through its Division of Global Migration and Quarantine.⁵⁵ Persons showing symptoms of illness are to be evaluated by CDC staff to determine if they should be taken to a hospital for medical evaluation and to get care as needed.⁵⁶ Asymptomatic persons are generally to be held under federal quarantine for 14 days from the time they left China if they have recently visited China’s Hubei Province. However, asymptomatic persons whose recent travels have not included Hubei Province, are asked to self-quarantine for 14 days.⁵⁷ Persons entering the United States who have been in Iran within the prior 14 days are subject to health monitoring.⁵⁸

Prior to the COVID-19 response, the HHS/CDC federal quarantine authority had not been used to restrict the movement of people since the early 1960s.⁵⁹ The CDC, however, regularly applies its quarantine authorities to assure that imports of animals, animal products, and other goods are free from diseases that could be transmitted to humans.⁶⁰ Authority to compel isolation (for sick human patients) and quarantine (for healthy exposed persons) has generally been exercised under state law.⁶¹

(Of note, in addition to announcing the United States' use of entry restrictions and quarantine authority on January 31, 2020, HHS Secretary Azar declared the COVID-19 outbreak to be a Public Health Emergency, pursuant to PHS Section 319.⁶² This declaration was not statutorily required for the abovementioned entry restrictions and quarantine requirements to go into effect, as each of these legal authorities is independent of the others. However, this declaration allows other actions, such as permitting states to reassign personnel on federal grants in order to respond to the emergency).

COVID-19 Travel Restrictions and Quarantine Requirements: Implementation

In large part, the exclusion of foreign nationals who have been in mainland China within the past 14 days has been carried out by commercial airlines, who are working with DHS to comply with new requirements, and many carriers have cancelled flights from mainland China.⁶³ Expanded exit screening of travelers in South Korea, Italy, and other countries, in addition to those traveling from China, are being put in place.⁶⁴

In addition, personnel from DHS components—namely Customs and Border Protection (CBP) and the Transportation Security Administration (TSA)—are involved in excluding foreign nationals from entry once travelers arrive at a port of entry in the United States, whether due to the January 31 and February 29 Presidential Proclamations or for unrelated reasons under immigration law. These flights are arriving in one of 11 U.S. airports (see text box).⁶⁵

These flights are arriving in one of 11 U.S. airports (see text box).⁶⁸

U.S. Airports Accepting Passengers Who Have Been in Mainland China within 14 Days

John F. Kennedy International Airport (JFK), New York Chicago O'Hare International Airport (ORD), Illinois San Francisco International Airport (SFO), California Seattle-Tacoma International Airport (SEA), Washington Daniel K. Inouye International Airport (HNL), Hawaii Los Angeles International Airport, (LAX), California Hartsfield-Jackson Atlanta International Airport (ATL), Georgia Washington-Dulles International Airport (IAD), Virginia Newark Liberty International Airport (EWR), New Jersey Dallas/Fort Worth International Airport (DFW), Texas Detroit Metropolitan Airport (DTW), Michigan.

Quarantine Requirements for Travelers Arriving from China

Upon arrival at one of the designated U.S. airports, the health status and travel history of individuals who have been in mainland China within the prior 14 days are evaluated to determine the need for mandatory quarantine (if they have been in Hubei Province within the prior 14 days); isolation (if they are symptomatic and/or test positive for coronavirus infection); or education and self-quarantine (if they have been elsewhere in mainland China within the prior 14 days). These passenger screenings have been conducted by personnel from CDC with assistance from CBP. The Department of State has also assisted American citizens, LPRs, and other persons who are permitted to return to the United States, by providing a number of repatriation airline flights, among other assistance.⁶⁹ According to CDC, as of February 23, “A total of 46,016 air travelers had been screened at the 11 U.S. airports to which all flights from China are being directed.”⁷⁰

Travelers designated for mandatory quarantine have generally been housed on military bases for a 14-day period. While in quarantine, the individuals are monitored and their care and basic needs attended to by personnel from CDC, the office of the HHS Assistant Secretary for Preparedness and Response (ASPR), officers of the U.S. Public Health Service

Notes: “When evacuees from Wuhan arrived at Travis Air Force Base on February 5, responders from the National Disaster Medical System (NDMS) and the U.S. Public Health Service Commissioned Corps were there to evaluate evacuees for symptoms of COVID19 and stood ready to help. The U.S. Department of Health and Human Services (HHS) is continuing to take steps to fight COVID-19 and keep Americans healthy.” Wuhan is the capital of Hubei Province in mainland China.

Figure 2. HHS Responders at Travis Air Force Base Taken February 5, 2020.

Individuals who self-quarantine are directed to monitor their health and remain away from public places where close contact may occur (e.g., workplaces) for 14 days from the time the person was possibly exposed. State or local health departments are to provide oversight for individuals who self-quarantine.⁷²

Potential Health Effects of Travel Restrictions and Quarantines

Proposals to restrict the movement of people from affected regions or countries are part of early discussions when novel communicable diseases arise. The World Health Organization (WHO) generally advises against nations imposing travel restrictions on other nations, citing limited evidence of the effectiveness of such measures in controlling outbreaks and the harmful economic effects they have on nations struggling with outbreaks.⁷³ On January 27, 2020, WHO stated, with respect to COVID-19, that it “advises against the application of any restrictions of international traffic based on the information currently

⁷¹ The U.S. Public Health Service Commissioned Corps and the National Disaster Medical System are described in CRS Report R43560, *Deployable Federal Assets Supporting Domestic Disaster Response Operations: Summary and Considerations for Congress*.

⁷² CDC, “Coronavirus Disease 2019 (COVID-19), Travel: Frequently Asked Questions and Answers,” accessed February 21, 2020, <https://www.cdc.gov/coronavirus/2019-ncov/travelers/faqs.html>.

⁷³ See, for example, World Health Organization (WHO), “No Rationale for Travel Restrictions,” May 1, 2009, in the context of the 2009 H1N1 influenza pandemic, https://www.who.int/csr/disease/swineflu/guidance/public_health/travel_advice/en/.

available on this event.”⁷⁴ However, on February 11, WHO issued more nuanced guidance, saying

Evidence on travel measures that significantly interfere with international traffic for more than 24 hours shows that such measures may have a public health rationale at the beginning of the containment phase of an outbreak, as they may allow affected countries to implement sustained response measures, and non-affected countries to gain time to initiate and implement effective preparedness measures. Such restrictions, however, need to be short in duration, proportionate to the public health risks, and be reconsidered regularly as the situation evolves.⁷⁵

WHO’s guidance then discusses the measures it recommends be taken in managing travelers before embarkation, en route, upon arrival and, if indicated, while in quarantine.

The effect of movement restrictions on the spread of communicable diseases is generally considered poorly understood for several reasons, including (1) limited contemporary examples for study; (2) the inherent variability in the natural progression of global disease outbreaks, even those caused by the same pathogen; (3) variation in actions taken by affected countries and restrictions imposed by other countries; and (4) difficulty in accounting for the effects of nongovernmental actions such as event cancellations and airline flight adjustments. In response to the emergence of COVID-19, China imposed sweeping internal movement restrictions,⁷⁶ a measure that is likely, in later analyses, to obscure or confound any additional transmission-damping effects that the U.S.-imposed travel restrictions may achieve.

Several studies have examined the potential effects of travel restrictions on disease spread, particularly looking at the global spread of influenza and at the outbreak of Severe Acute Respiratory Syndrome (SARS) in 2002-2003. Of note, these analyses sometimes indicated delays in the speed of spread of an outbreak. However, the effect of travel restrictions on the ultimate geographic spread of the outbreak—or on the reduction of overall morbidity or mortality—is unclear, and the evidence base is limited. Some studies have found no effect of travel restrictions on overall morbidity and mortality of infectious disease.⁷⁷ Others have found that very strict travel restrictions may effectively prevent the spread of disease (i.e., complete border closure) or that travel restrictions might be more effective when combined with other infection control measures, such as quarantine and isolation.⁷⁸ In particular, compulsory movement restrictions may rely on public support in order to be effective, as well as to avoid discrimination and loss of public trust. Many suggest that if

⁷⁴ WHO, “Updated WHO Advice for International Traffic in Relation to the Outbreak of the Novel Coronavirus 2019-nCoV,” January 27, 2020, https://www.who.int/ith/2019-nCoV_advice_for_international_traffic/en/.

⁷⁶ Michael Levenson, “Scale of China’s Wuhan Shutdown Is Believed to Be without Precedent,” *The New York Times*, January 22, 2020. Wuhan is the capital of Hubei Province in mainland China.

⁷⁷ Several such studies are discussed in Julia Belluz and Steven Hoffman, “The evidence on travel bans for diseases like coronavirus is clear: They don’t work,” *Vox*, January 23, 2020, <https://www.vox.com/2020/1/23/21078325/wuhanchina-coronavirus-travel-ban>.

⁷⁸ Sukhyun Ryu, Huizhi Gao, Jessica Y. Wong, et al., “Nonpharmaceutical Measures for Pandemic Influenza in Nonhealthcare Settings—International Travel-Related Measures,” *Emerging Infectious Diseases*, vol. 26, no. 5 (May 2020).

public support and trust are essential in any case, enlisting movement restriction through voluntary measures may be just as effective, with less societal disruption.⁷⁹

Quarantine has a long history as a disease control measure, substantially predating the “germ theory” of infectious disease embraced in the late 19th century. According to CDC,

The practice of quarantine, as we know it, began during the 14th century in an effort to protect coastal cities from plague epidemics. Ships arriving in Venice from infected ports were required to sit at anchor for 40 days before landing. This practice, called quarantine, was derived from the Italian words *quaranta giorni* which mean 40 days.⁸⁰

Quarantine is considered a social distancing measure in public health, along with isolation, contact tracing, and measures to avoid crowding (i.e., school closures). Similar to the studies on movement restrictions, the precise effect of social distancing measures on the spread of infectious disease can be difficult to measure and the evidence base is limited.⁸¹ Yet, social distancing measures were some of the primary means by which the 2003 SARS outbreak in China was contained and are generally considered fundamental tools of infection control in public health.

Medical Countermeasures

Potential Products for Use in the COVID-19 Response

Medical countermeasures (MCMs) are medical products that may be used to treat, prevent, or diagnose conditions associated with emerging infectious diseases or chemical, biological, radiological, or nuclear (CBRN) threats. Examples of MCMs include biologics (e.g., vaccines, monoclonal antibodies), drugs (e.g., antimicrobials, antivirals), and devices (e.g., diagnostic tests and general personal protective equipment such as gloves, respirators/masks, and gowns).⁸² FDA regulates MCMs domestically. Currently, there are no FDA-approved MCMs specifically for COVID-19, although FDA has authorized the use of *unapproved* diagnostic tests, including via Emergency Use Authorization (EUA).⁸³ Federal agencies, pharmaceutical and biotech companies, nongovernmental organizations, and global regulators have been working to expedite the development and availability of MCMs for 2019-nCoV. Examples of such efforts include the following:

⁷⁹ Francesca Matthews Pillemer et al., “Predicting Support for Non-pharmaceutical Interventions during Infectious Outbreaks: A Four Region Analysis,” *Disasters*, vol. 39, no. 1, pp. 125-145, January 2015, <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4355939/>.

Diagnostics

As summarized earlier, CDC developed the 2019-nCoV Real-Time RT-PCR Diagnostic Panel for which FDA issued an EUA on February 4, 2020 (EUAs are described in more detail below).⁸⁴ The CDC test is a “test kit,” meaning it is manufactured, assembled, and then may be shipped for use by multiple laboratories. In contrast, many diagnostic tests are “laboratory-developed tests,” meaning that they are developed, validated, and used in a single laboratory. Generally, the FDA waives most regulatory requirements (e.g., premarket review) for LDTs, but nevertheless, LDTs may only be used with authorization (an EUA) during an emergency declaration pursuant to FFDCA Section 564.

On February 29, 2020, as problems with the roll-out of the CDC-developed diagnostic test continued, FDA announced a new policy to immediately leverage LDTs developed in high-complexity commercial, reference, and clinical laboratories nationwide to expand testing capacity. Specifically, the new guidance from the agency allows the nation’s CLIA-certified high-complexity laboratories that have developed and validated their own COVID-19 diagnostics to begin to use the tests while the laboratory is preparing, and FDA is reviewing, their EUA submissions.⁸⁵ The FDA guidance recommends that laboratories have 15 days after validating their test to submit their EUA application to the FDA, and recommends confirming the test’s first five negative and positive results against an EUA-authorized diagnostic. According to FDA, it “does not intend to object to the use of these tests for clinical testing while the laboratories are pursuing an EUA with the FDA. Importantly, this policy only applies to laboratories that are certified to perform high-complexity testing consistent with requirements under Clinical Laboratory Improvement Amendments.”⁸⁶

Several federal agencies are working with industry partners to develop rapid diagnostic point-of care tests for COVID-19, including NIH, particularly through the National Institute of Allergy and Infectious Diseases (NIAID); ASPR, through the Biomedical Advanced Research and Development Authority (BARDA); and the Department of Defense (DOD).⁸⁷ On February 5, 2020, BARDA announced an Easy Broad Agency Announcement (EZ-BAA) to solicit applications for development funding of COVID-19 molecular diagnostics. The submissions must have a viable plan to meet requirements for the FDA to consider EUA within 12 weeks of an award.⁸⁸

Therapeutics

Research and development into several treatment strategies for COVID-19 are underway by federal agencies, international partners, and industry. Drawing from research on the SARS and MERS coronaviruses, NIAID is assessing potential treatment strategies such as antiviral drugs and animal models that can be used to test potential MCMs. In addition, NIAID is developing assays and other research tools to study COVID-19.⁸⁹ In February 2020, BARDA announced that it would expand existing collaborations with Regeneron Pharmaceuticals Inc. and Janssen Research and Development to develop COVID-19 therapeutics.⁹⁰

Scientists in China are testing drugs currently approved for treatment of HIV, influenza (flu), and malaria for potential effectiveness against COVID-19.⁹¹ For example, Chinese authorities have reportedly recommended AbbVie's HIV drug Kaletra to treat patients, while the drug undergoes clinical testing.⁹² Johnson & Johnson has reportedly provided its HIV drug Prezcoibix to China to test as a potential treatment as well.⁹³ Scientists are also testing many experimental treatments in the research pipeline.⁹⁴ For example, Gilead is working with health authorities in China to determine whether its experimental antiviral drug Remdesivir can safely and effectively treat COVID-19.⁹⁵ In the United States, a clinical trial evaluating the safety and effectiveness of Remdesivir has begun at the University of Nebraska Medical Center (UNMC) in Omaha. The trial is sponsored by NIAID.⁹⁶

Vaccines

At least eight different COVID-19 vaccine development initiatives among federal agencies, industry, research institutions, and philanthropies have been announced.⁹⁷ Of note, the NIAID Vaccine Research Center (VRC) is collaborating with the drug company Moderna and the Coalition for Epidemic Preparedness Innovations (CEPI) to advance a vaccine candidate. Moderna expects this vaccine to enter phase 1 clinical testing in the spring of 2020.⁹⁸ CEPI is also supporting vaccine development by the University of Queensland

(Australia) and the drug companies GlaxoSmithKline and Inovio.⁹⁹ BARDA has announced vaccine development partnerships with Sanofi and Johnson & Johnson.¹⁰⁰

Status of MCM Development

MCM development for COVID-19 has exceeded the pace of MCM development for previous infectious disease outbreaks; however, it is still uncertain if the products will be available in time to curb spread of the virus. Diagnostic tests for COVID-19 were developed by CDC and other global public health laboratories in a few weeks after COVID-19 was first reported, compared to almost six months for the 2002-2003 SARS outbreak.¹⁰¹ The NIAID supported Moderna vaccine is expected to begin phase 1 clinical trials in late April. In comparison, it took 20 months for NIAID to get a SARS vaccine into phase 1 clinical trials.¹⁰² However, vaccine development is difficult and only a handful of new vaccines have been licensed in recent decades, despite ongoing efforts to develop vaccines for infectious diseases such as MERS and HIV.¹⁰³ Additionally, the NIAID and Moderna vaccine relies on a new technology that no FDA-approved vaccine has ever used.¹⁰⁴ An FDA official has reportedly asserted that therapeutics for COVID2019 are likely to be available more quickly than a vaccine.¹⁰⁵

FDA Emergency Use Authorization (EUA)

Clinical testing and the FDA review process typically take several years, so it will take time for MCMs in development to reach the commercial market. However, experimental products may become available in the United States prior to FDA approval pursuant to an EUA. FDA encourages industry and government sponsors (e.g., CDC) to engage with FDA prior to submitting a formal request for an EUA, if possible.

Under most circumstances, drugs, medical devices, and biologics may be introduced into interstate commerce only if they have been approved, cleared, or licensed by FDA. Under certain circumstances, however, FDA may permit a medical product to be provided to patients outside the standard regulatory framework, including through issuance of an EUA. In the absence of an approved MCM for COVID-19, FDA may enable access to investigational

MCMs by issuing an EUA, if the HHS Secretary declares that circumstances exist to justify the emergency use of an *unapproved product* or an *unapproved use of an approved medical product*.¹⁰⁶ The HHS Secretary's declaration must be based on one of four determinations; for example, a determination that there is an actual or significant potential for a public health emergency that affects or has significant potential to affect national security or the health and security of U.S. citizens living abroad.¹⁰⁷ Following the HHS Secretary's declaration, FDA, in consultation with ASPR, NIH, and CDC, may issue an EUA authorizing the emergency use of a specific drug, device, or biologic, provided that certain criteria are met (e.g., that there is no adequate, approved, and available alternative to the product).¹⁰⁸

On February 4, 2020, the HHS Secretary determined that there is a public health emergency that has a significant potential to affect national security or the health and security of U.S. citizens living abroad, and that involves the COVID-2019.¹⁰⁹ This emergency determination by the HHS Secretary is distinct from the Public Health Emergency declaration made pursuant to PHSA Section 319. On the basis of this determination, on February 4, 2020, the HHS Secretary declared that circumstances exist justifying the authorization of emergency use of in vitro diagnostics for the detection and/or diagnosis of COVID-2019. This declaration allowed FDA to issue an EUA authorizing the emergency use of the CDC-developed diagnostic test for COVID-2019. Pursuant to the same February 4, 2020 determination, on March 2, 2020, the HHS Secretary declared that circumstance exist justifying the emergency use of personal respiratory protective devices during the COVID-19 outbreak. This declaration allowed FDA to issue a second EUA—this one authorizing the emergency use of certain respirators in health care settings by health care personnel “to prevent wearer exposure to pathogenic biological airborne particulates during FFR [filtering facepiece respirator] shortages resulting from the COVID-19 outbreak.”¹¹⁰

Health System Preparedness

Health Care Capability and Capacity

There is concern that if COVID-19 spreads widely in the community, it will overwhelm the health care system's ability to care for patients and prevent further spread of the disease.

¹⁰⁶ 21 U.S.C. §360bbb-3. For additional information, see CRS In Focus IF10745, *Emergency Use Authorization and FDA's Related Authorities*.

¹⁰⁷ 21 U.S.C. §360bbb-3(b)(1).

¹⁰⁸ 21 U.S.C. §360bbb-3(c).

¹⁰⁹ This determination, made pursuant to Section 564(b)(1)(C) of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. §360bbb-3(b)(1)(C)), is noted on page 1 of the letter of authorization from FDA to CDC, advising of the authorization for emergency use of the CDC-developed diagnostic test. This letter is available at “Novel coronavirus (COVID-2019) EUA Information” on the FDA web page “Emergency Use Authorization,” <https://www.fda.gov/emergencypreparedness-and-response/mcm-legal-regulatory-and-policy-framework/emergency-use-authorization>. See also footnote 84.

¹¹⁰ FDA, “Coronavirus (COVID-19) Update: FDA and CDC take action to increase access to respirators, including N95s, for health care personnel,” March 2, 2020, <https://www.fda.gov/news-events/press-announcements/coronaviruscovid-19-update-fda-and-cdc-take-action-increase-access-respirators-including-n95s>. The letter of authorization from FDA to CDC, advising of the authorization for emergency use of certain eligible respirators is available at “Novel coronavirus (COVID-2019) EUA Information” on the FDA web page “Emergency Use Authorization,” <https://www.fda.gov/emergency-preparedness-and-response/mcm-legal-regulatory-and-policy-framework/emergency-use-authorization>.

Given that it is currently flu season, many health care facilities are already at or near patient capacity.

The ASPR is the principal advisor to the HHS Secretary on the public health and medical preparedness and response for public health emergencies.¹¹¹ CDC is the nation's leading public health agency. Since 2002, the ASPR and CDC have funded grants to states for health system and public health preparedness, respectively.¹¹² These grants have fostered nationwide development of several response capabilities that would be called upon for a successful response to the COVID19 threat, including the following:

- **Medical surge:** "...the ability to provide adequate medical evaluation and care during events that exceed the limits of the normal medical infrastructure of an affected community. It encompasses the ability of the health care system to endure a hazard impact, maintain or rapidly recover operations that were compromised, and support the delivery of medical care and associated public health services, including disease surveillance, epidemiological inquiry, laboratory diagnostic services, and environmental health assessments."¹¹³ ASPR and CDC are projecting the potential long-term impact of COVID-19 and assessing the capacity of the health care system to respond to a larger outbreak. A sustained response could engage the Regional Treatment Network for Ebola and Other Special Pathogens, a tiered health system response network developed with funding provided by Congress for response to the Ebola outbreak in 2015.¹¹⁴
- **Nonpharmaceutical interventions (NPI):** "...actions that people and communities can take to help slow the spread of illness or reduce the adverse impact of public health emergencies. This capability focuses on communities, community partners, and stakeholders recommending and implementing [NPI] in response to the needs of an incident, event, or threat."¹¹⁵ Interventions may include isolation, quarantine, restrictions on movement and travel advisories or warnings, social distancing, external decontamination, hygiene, and precautionary protective behaviors.
- **Medical countermeasure dispensing and administration:** "...the ability to provide medical countermeasures to targeted population(s) to prevent, mitigate, or treat the adverse health effects of a public health incident. This capability focuses on dispensing and administering medical countermeasures, such as vaccines, antiviral drugs, antibiotics..."¹¹⁶ The Strategic National Stockpile (SNS), managed by ASPR, provides select medicines and medical supplies during public health emergencies when local supply chains are disrupted.¹¹⁷

¹¹⁶ *Ibid.*, p. 80.

¹¹⁷ HHS, "Strategic National Stockpile," <https://www.phe.gov/about/sns/Pages/default.aspx>.

The National Health Security Preparedness Index (NHSPI, or the Index), a public-private partnership begun in 2013, currently assesses preparedness, using 140 measures, across all 50 states and the District of Columbia.¹¹⁸ In its latest comprehensive report, for 2017, NHSPI found overall incremental improvements over earlier years in capabilities such as disease surveillance and medical countermeasures management. However, the report highlighted differing preparedness levels among states, stating

Large geographic areas in the Deep South and Mountain West trail the rest of the nation in health security, leaving many low-income populations and rural residents at elevated risk.¹¹⁹

In addition, measures of health care delivery—for example, the number of certain types of health care providers (including mental health providers) per unit of population, access to trauma centers, the extent of preparedness planning in long-term care facilities, and uptake of electronic health record systems—and of community planning and engagement—for example, the degree of coordination between public health authorities and the health care system—continued to yield the lowest scores among the indicators across the United States.

Supply Chain Management

ASPR, CDC, and FDA play roles in protecting against and preparing for the potential impact of the COVID-19 virus on the medical product supply chain, including shortages of critical drugs and medical devices such as personal protective equipment (PPE). ASPR, FDA, and CDC have indicated that they are working with health care and/or industry partners to ensure an adequate supply of medical products needed to contain the outbreak and to identify potential disruptions or shortages.¹²⁰ A chief concern in supply chain management is that many medical products or drugs are manufactured, at least in part, in China, the epicenter of the current outbreak.¹²¹

By law, drug manufacturers are required to notify FDA of a permanent discontinuance of or interruption in the manufacture of a drug that is likely to lead to a disruption in its supply.¹²² Based on the reported information, FDA may take various actions to mitigate or prevent a drug shortage from occurring, such as expediting applications for approval from other manufacturers and allowing for the temporary importation of unapproved drugs.¹²³ Currently, there are no parallel reporting requirements for medical devices.

Some have concerns with respect to FDA's ability to inspect and monitor compliance of FDA-regulated products manufactured overseas and particularly in China. As of February 24,

¹²³ 21 U.S.C. §356c(g), 21 U.S.C. §381(d).

2020, FDA is not conducting inspections in China due to the State Department travel advisory. Inspections in China scheduled for February 2020 have been either postponed, or the agency is using different means to obtain information to inform regulatory decisions about FDA-regulated products manufactured in these facilities.¹²⁴ While there are no FDA-licensed vaccines, gene therapies, or blood derivatives manufactured in China, the raw materials used to produce these biologics are manufactured in China and other countries in Southeast Asia.¹²⁵ In addition, according to FDA data, 72% of facilities that manufacture active pharmaceutical ingredients (APIs) for drugs are located outside of the United States, with 13% of facilities in China; 53% of facilities manufacturing finished drugs are located outside of the United States, with 7% of facilities in China.¹²⁶ These numbers are not reflective of product volume. FDA is not able to determine what volume of APIs being used for the U.S. market is from China, as manufacturers are not required to report this information to the agency.

Response Funding

CDC and other federal agencies may have the authority needed to respond to the COVID-19 epidemic, but their ability to act may be affected by the availability of appropriations. Annual appropriations and standing transfer authority provide the HHS Secretary with some flexibility.¹²⁷ Upon a declaration of a Public Health Emergency pursuant to PHSA Section 319—which HHS Secretary Azar made on January 31, 2020—HHS may access a Public Health Emergency Fund,¹²⁸ but the fund does not have an available balance at this time. Separately, funding has generally not been available under the Robert T. Stafford Disaster Relief and Emergency Assistance Act (the Stafford Act) for the response to infectious disease outbreaks. As a result, Congress and the President provided supplemental appropriations for the response to the recent Ebola and Zika virus outbreaks in FY2015 and FY2016.¹²⁹

¹²⁵ FDA, “FDA’s Actions in Response to 2019 Novel Coronavirus at Home and Abroad,” February 14, 2020, <https://www.fda.gov/news-events/press-announcements/fdas-actions-response-2019-novel-coronavirus-home-andabroad>.

¹²⁶ FDA, Testimony of Dr. Janet Woodcock, Director the Center for Drug Evaluation and Research, “Securing the U.S. Drug Supply Chain: Oversight of FDA’s Foreign Inspection Program,” December 10, 2019, <https://www.fda.gov/newsevents/congressional-testimony/securing-us-drug-supply-chain-oversight-fdas-foreign-inspection-program-12102019>.

¹²⁷ Annual appropriations acts give the HHS Secretary limited authority to transfer funds from one budget account to another within the department. For instance, a provision in the FY2020 HHS appropriations act (P.L. 116-94, Division A, Title II, §205) generally allows the Secretary to transfer up to 1% of the funds from any given account. However, in general, a recipient account may not be increased by more than 3%. Congressional appropriators must be notified in advance of any transfer. Another FY2020 appropriations provision (P.L. 116-94, Division A, Title V, §514) addresses the Secretary’s authority to reprogram funds from one program, project, or activity in a given budget account to a different program, project, or activity within the same budget account. This provision places certain limits on such actions and clarifies the circumstances in which appropriations committees must be consulted in advance. (See P.L. 115-245).

¹²⁸ See HHS, “Legal Authority with Declaration of Public Health Emergency,” <https://www.phe.gov/Preparedness/support/secauthority/Pages/default.aspx#phe>.

¹²⁹ Rebecca Katz, Aurelia Attal-Juncqua, and Julie E. Fischer, “Funding Public Health Emergency Preparedness in the United States,” *American Journal of Public Health*, vol. 107, suppl. 2, pp. S148-S152, September, 2017, <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5594396/>.

In 2018, Congress established an Infectious Diseases Rapid Response Reserve Fund (IDRRRF) for CDC, providing appropriations of \$50 million for FY2019 (P.L. 115-245) and \$85 million for FY2020 (P.L. 116-94), available until expended.¹³⁰ These funds may be made available for an infectious disease emergency if the HHS Secretary either (1) declares a Public Health Emergency pursuant PHSA Section 319, or (2) determines that the infectious disease outbreak has significant potential to occur and, if it occurs, the potential to affect national security or the health and security of U.S. citizens, both domestically and abroad.

Before HHS Secretary Azar declared the COVID-19 outbreak to be a Public Health Emergency under PHSA Section 319, he issued a determination on January 25, 2020, allowing the allotment of \$105 million from the IDRRRF for the COVID-19 response.¹³¹ Secretary Azar had previously determined that the U.S. response to the Ebola outbreak in the Democratic Republic of Congo allowed the use of up to \$30 million from the IDRRRF. If both the Ebola and COVID-19 amounts are fully used, all funds currently in the IDRRRF would be exhausted.¹³² On February 2, 2020, HHS reportedly notified Congress of its intention to use the Secretary's standing authority to transfer up to \$136 million for COVID-19 response efforts, of which \$75 million would be made available to CDC, \$52 million for ASPR, and \$8 million for the HHS Office of Global Affairs.¹³³ Since then, Secretary Azar has reportedly "told lawmakers that the administration has now spent or obligated the entirety of \$105 million [from the IDRRRF] and is now moving into previously announced transfers of \$136 million from other programs."¹³⁴

CDC has an additional source of emergency support through the CDC Foundation, a 501(c)(3) public charity established by Congress "to support and carry out activities for the prevention and control of diseases, disorders, injuries, and disabilities, and for promotion of public health."¹³⁵ The CDC Foundation activated its Emergency Response Fund (ERF) to support COVID-19 response on January 27, 2020, as requested by CDC.¹³⁶ Funds have been donated to the ERF for this response by the Robert Wood Johnson Foundation, among others. Although the support provided by the foundation for outbreak response has been modest compared with supplemental appropriations, the foundation has greater spending flexibility and can sometimes procure response supplies and services more quickly than CDC through federal procurement processes.¹³⁷

On February 24, 2020, the Administration asked Congress for an emergency supplemental appropriation of \$1.25 billion for COVID-19 response efforts. The Administration also asked Congress to allow re-purposing of another \$1.25 billion in existing

¹³⁰ The IDRRRF authority is codified at 42 U.S.C. §247d-4a.

Chapter 384

GLOBAL ECONOMIC EFFECTS OF COVID-19: IN BRIEF*

***James K. Jackson, Andres B. Schwarzenberg,
Martin A. Weiss and Rebecca M. Nelson***

OVERVIEW

Since the World Health Organization (WHO) first declared COVID-19 a world health emergency in January 2020, the virus has been detected in over 150 countries and almost all U.S. states.¹ The infection has sickened more than 200,000 people, with thousands of fatalities.

On March 11, the WHO announced that the outbreak was officially a pandemic, the highest level of health emergency.² During that time, it has become clear that the outbreak is negatively impacting global economic growth.³ The virus is affecting a broad swath of economic activities, from tourism, medical supplies and other global value chains, consumer electronics, and financial markets to energy, food, and a range of social activities, to name a few. Without a clear understanding of when the health and economic effects may peak economic forecasts must necessarily be considered preliminary. Efforts to reduce social interaction to contain the spread of the virus are disrupting the daily lives of most Americans.

On March 2, 2020, the Organization for Economic Cooperation and Development (OECD) released its revised economic outlook and suggested that global economic growth could decline by 0.5% in 2020 to 2.4% if the economic effects of the virus peak in the first

* This is an edited, reformatted and augmented version of a Congressional Research Service publication R46270, prepared for Members and Committees of Congress dated March 18, 2020.

³ Mapping the Spread of the Coronavirus.

quarter of 2020⁴ (see Table 1). If the effects of the virus do not peak in the first quarter, which now seems unlikely, the OECD estimates that global economic growth in 2020 could be reduced by half, or 1.5%.

Concerns over economic and financial risks have pushed investors to search out safe-haven investments such as the benchmark U.S. Treasury 10-year security, which experienced a historic drop in yield to below 1% on March 3, 2020 (the price and yield of a bond are inversely related).⁵ The yield dropped again to historic levels on March 6, 2020, and March 9, 2020, as investors moved out of stocks and into bonds due to concerns over declines in major stock indices and expectations that the Federal Reserve would lower interest rates for a second time in March 2020.⁶ In overnight trading on March 8, 2020, and again on March 11, 2020, March 13, 2020, and March 15, 2020, U.S. stock market indices moved sharply, triggering automatic circuit breakers designed to halt trading if the indices rise or fall by more than 5% when markets are closed.⁷ Financial markets from the United States to Asia and Europe are volatile as investors are concerned that the virus is creating a global issue with few metrics to indicate how prolonged and expansive the economic effects may be.⁸ Similar to the 2008-2009 global financial crisis, central banks are finding themselves put in the position of being the lender of last resort. During the financial crisis, central banks intervened to restart credit and spending. In the current environment, however, central banks are attempting to address financial market volatility that reflects the underlying economic uncertainty caused by the viral outbreak. The virus is also affecting global politics as world leaders are cancelling international meetings⁹ and some nations reportedly are stoking conspiracy theories that shift blame to other countries.¹⁰

The challenge for policymakers is to implement targeted policies that address what are expected to be short-term problems without creating distortions in economies that can outlast the impact of the virus itself. Policymakers are being overwhelmed by the quickly changing nature of the crisis that has compounded a health issue with what could become a global trade and economic crisis whose potential effects on the global economy are rapidly growing. In addition, many policymakers are constrained in their response to the crisis, with little flexibility for monetary and fiscal support, given the broad-based synchronized slowdown in global economic growth, especially in manufacturing and trade, which had developed prior to the viral outbreak.

ESTIMATED ECONOMIC EFFECTS

The economic situation remains highly fluid. Uncertainty about the length and depth of the virus-related economic effects are fueling perceptions of risk and volatility in financial markets and corporate decisionmaking. In addition, uncertainties concerning the virus and the effectiveness of public policies intended to curtail its spread are adding to market volatility.

The OECD also estimates that increased direct and indirect economic costs through global supply chains reduced demand for goods and services, and that declines in tourism and business travel mean that, “the adverse consequences of these developments for other countries (non-OECD) are significant.”¹¹ Global trade, measured by trade volumes, slowed in the last quarter of 2019 and was expected to decline further in 2020 as a result of weaker global economic activity associated with the viral outbreak, which is reducing economic activity in various sectors, including ports and the shipping industry.¹²

¹¹ Ibid., p. 2.

¹² Ibid., p. 4.

COMPARING THE CURRENT CRISIS AND THE 2008 CRISIS

Sharp declines in the stock market and broader financial sector turbulence; interest rate cuts and large-scale Federal Reserve intervention; and discussions of massive government stimulus packages have led some observers to compare the current market reaction to that experienced a little over a decade ago. There are similarities and important differences between the current economic crisis and the global financial crisis of 2008/2009. Foremost, the earlier crisis was rooted in structural weakness in the U.S. financial sector. Following the collapse of the U.S. housing bubble, it became impossible for firms to identify demand and hold inventories (across many sectors (construction, retail, etc.)). This led to massive oversupply and sharp retail losses which extended to other sectors of the U.S. economy and eventually the global economy. Moreover, financial markets across countries were linked together by credit default swaps. As the crisis unfolded, large numbers of banks and other financial institutions were negatively affected, raising questions about capital sufficiency and reserves. The crisis, then quickly engulfed credit-rating agencies, mortgage lending companies and the real estate industry broadly. Market resolution came gradually with a range of monetary and fiscal policy measures that were closely coordinated at the global level. These were focused on putting a floor under the falling markets, stabilizing banks, and shoring up investor confidence to get spending started again. Starting in September 2007, The Federal Reserve cut interest rates from over 5% in September 2007 to between 0 and 0.25% before the end of the 2008.

Once interest rates approached zero, the Fed turned to other so-called “unconventional measures” including targeted assistance to financial institutions, including encouraging Congress to pass the Troubled Asset Relief Program (TARP) and the Term Asset Backed Security Loan Facility (TALF) to prevent the collapse of the financial sector and boost consumer spending. Other measures included forced bank capitalizations (or bank nationalizations in other countries), swap arrangements between the Federal Reserve and the European Central Bank and smaller central banks, and so-called “quantitative easing” to boost the money supply. On a global level, the United States and other countries tripled the resources of the IMF (from \$250 billion to \$750 billion) and coordinated domestic stimulus efforts.

Unlike the 2008 crisis, the current crisis began as a supply shock. As the global economy has become more interdependent in recent decades, most products are produced as part of a global value chain (GVC), where an item such as a car or mobile device consists of parts manufactured all over the world, and involving multiple border crossings before final assembly. The earliest implications of the current crisis came in January as plant closures in China and other parts of Asia led to interruptions in the supply chain and concerns about dwindling inventories. As the virus spread from Asia to Europe, the crisis switched from supply concerns to a broader demand crisis as the measures being introduced to contain the spread of the virus (social distancing, travel restrictions, cancelling sporting events, closing shops and restaurants, and mandatory quarantine measures) prevent most forms of economic activity from occurring. Thus, unlike the 2008 crisis response, which involved liquidity and solvency-related policy measures to get people spending again, the current crisis is related to the amount of operating capital in the economy. While larger firms may have sufficient capital to wait out a crisis, many aspects of the economy (such as restaurants or retail operations) operate on very tight margins and would likely not be able to pay employees after closures lasting more than a few days. Many people will also need to balance child care and work during quarantine or social distancing measures.

During this type of crisis, while monetary policy measures play a part -- and the Federal Reserve has once again cut rates to near zero -- they cannot compensate for the physical interaction that the global economy is dependent upon. As a result, fiscal stimulus will likely play a relatively larger role in this crisis in order to prevent personal and corporate bankruptcies during the peak crisis period. Efforts to coordinate U.S. and foreign economic policy measures will also have an important role in mitigating the scale and length of any global economic downturn.

In addition, the OECD argues that China’s emergence as a global economic actor marks a significant departure from previous global health episodes. China’s growth in combination with globalization and the interconnected nature of economies through supply chains and foreign investment magnify the cost of containing the spread of the virus through quarantines

and restrictions on labor mobility and travel.¹³ China's global economic role and globalization more broadly mean that trade is playing a role in spreading the economic effects of COVID-19 through three channels: directly through supply chains as reduced economic activity is spread from intermediate goods producers to finished goods producers; as a result of a drop in economic activity, which reduces demand for goods in general, including imports; and through reduced trade with commodity exporters that supply producers, which, in turn, reduces their imports and negatively affects trade and economic activity of exporters.

Initially, the economic effects of the virus were expected to be a short-term supply issue as factory output fell because workers were quarantined to reduce the spread of the virus through social interaction. The drop in economic activity, initially in China, created larger supply issues as firms experienced delays in supplies in intermediate and finished goods through supply chains. Concerns have grown, however, that the virus-related supply shock is creating a more prolonged demand shock as reduced activity by consumers and businesses lead to a lower rate of economic growth. As demand shocks unfold, businesses experience a decline in activity, reduced profits, and potentially escalating and binding credit and liquidity constraints. While manufacturing firms are experiencing supply shocks through their supply chains, reduced consumer activity through social distancing is affecting the services sector of the economy, which accounts for two-thirds of U.S. economic output. In this environment, manufacturing and service firms are hoarding cash, which affects market liquidity. In response central banks have taken measures to provide financial markets with liquidity.

If the economic effects persist, contagion issues can spread the economic effects widely and affect an ever-broadening group of firms and households. This potentially can increase liquidity constraints and credit market tightening in global financial markets as firms hoard cash, with negative fallout effects on economic growth. In some financial markets, fund managers have started selling government securities to increase their cash reserves, pushing down government bond prices. At the same time, financial markets are factoring in an increase in government bond issuance in the United States and Europe as government debt levels rise to meet spending obligations during an expected slowdown in economic activity and efforts to fight the effects of COVID-19. Unlike the 2008 financial crisis, reduced demand by consumers, labor market issues, and a reduced level of activity among businesses, rather than risky trading by global banks, has led to corporate credit issues. The market dynamics have led some observers to question if these events mark the beginning of a full-scale global financial crisis.¹⁴

Liquidity and credit market issues present policymakers with a different set of challenges than addressing supply-side constraints. As a result, the focus of government policy has expanded from a health issue to macroeconomic and financial market issues that are being addressed through a combination of monetary, fiscal, and other policies. Essentially, while businesses are attempting to address worker and output issues at the firm level, national leaders are attempting to implement fiscal policies to assist workers and businesses that are facing financial strains, and central bankers are adjusting monetary policies to address mounting credit market issues. So far, households have been affected primarily through a loss of income, compared with the 2008-2009 financial crisis in which households experienced a

sudden and large loss in the value of their assets, largely through a decline in the market value of their primary residence.

In many cases, national fiscal policies that might be employed to address demand issues are already constrained by high government debt levels; similarly, recent monetary policies have generally been accommodative, which leaves central banks little room for additional cuts in interest rates. In addition, in the current environment, even traditional policy tools, such as monetary accommodation, apparently are not being processed by markets in a traditional manner, with equity market indices displaying heightened, rather than lower, levels of uncertainty following the Federal Reserve's cut in interest rates. Such volatility is adding to uncertainties about what governments can do to address weaknesses in the global economy.

Before the COVID-19 outbreak, the global economy was struggling to regain a broad-based recovery as a result of the lingering impact of growing trade protectionism, trade disputes among major trading partners, falling commodity and energy prices, and economic uncertainties in Europe over the impact of the UK withdrawal from the European Union. Individually, each of these issues presented a solvable challenge for the global economy. Collectively, however, the issues weakened the global economy and reduced the available policy flexibility of many countries, especially among the leading developed economies. In this environment, COVID-19 could have an outsized impact. While the level of economic effects will eventually become clearer, the response to the virus could have a significant and enduring impact on the way businesses organize their work forces, global supply chains, and how governments respond to a global health crisis.¹⁵

POLICY RESPONSE

In response to growing concerns over the global economic impact of the virus, G-7 finance ministers and central bankers released a statement on March 3, 2020, indicating they will “use all appropriate policy tools” to sustain economic growth.¹⁶ The Finance Ministers also pledged fiscal support to ensure health systems could sustain efforts to fight the outbreak.¹⁷ Following the G-7 statement, the U.S. Federal Reserve (Fed) lowered its federal funds rate by 50 basis points, or 0.5%, to a range of 1.0% to 1.25% due to concerns about the “evolving risks to economic activity of the coronavirus.”¹⁸ At the time, the cut was the largest one-time reduction in the interest rate by the Fed since the financial crisis of 2008.

The United States

In a sign of growing concern over strains in financial markets, on March 12, 2020, the Federal Reserve announced it will supply liquidity to the financial system by providing \$5 trillion through a series of funding operations that will add to current monthly funding operations targeted at increasing reserves in the banking system and reducing stress in short-term funding market and in trading U.S. Treasury securities. Corporate bond markets halted activity on March 11, 2020, as companies drew on revolving credit facilities from banks to ensure they had enough cash on hand to sustain their operations during a prolonged slump in economic activity and potential credit tightening by banks.

In addition, banks and financial institutions that deal in trading U.S. Treasury securities had begun to pull back from facilitating trades to protect themselves from market volatility, increasing costs to traders who profit from the difference between buying Treasury securities and then selling futures contracts.¹⁹ The Federal Reserve reportedly will provide \$1 trillion in short-term lending to banks to sustain lending between banks, because credit markets had begun to freeze up. In addition, the Federal Reserve opened a financial crisis-era facility to acquire corporate bonds in the commercial paper (CP) market, which is used by firms to raise cash by selling short-term debt.²⁰ Banks have become reluctant to acquire the securities over concerns that markets that trade in CP will be frozen.²¹ The Fed also indicated that it will provide a series of \$500 billion injections of funds into the repo (repurchase) market, where investors borrow cash in exchange for high-quality collateral like Treasury securities.²²

In an additional step, the Federal Reserve cut interest rates by 100 basis points (1.0%) on March 15, 2020, to a range of 0% to 0.25%, because it determined that “....The coronavirus outbreak has harmed communities and disrupted economic activity in many countries, including the United States. Global financial conditions have also been significantly affected.”²³ The Federal Reserve announced that it was providing an additional \$700 billion in asset purchases (Treasury securities and mortgage-backed securities), expanding repurchase operations, extending dollar swap lines with foreign banks (Canada, the UK, Japan and Europe, including the Swiss National Bank), and opened its discount window to commercial banks and urged banks to use their own capital and liquidity buffers to ease household and business lending. In its statement, the Federal Reserve announced that it was prepared to use its “full range of tools to support the flow of credit to households and businesses....” The coordinated central bank actions were intended to calm global financial markets after a week of greater than usual volatility. On March 17, 2020, the Federal Reserve opened a new financing facility for the 24 primary dealers in U.S. Treasury securities that allows them to borrow cash secured against some stocks, municipal debt and higher-rated corporate bonds.

In terms of a fiscal stimulus, the House passed H.R. 6074 on March 5, 2020, to appropriate \$8.3 billion in emergency funding to support efforts to fight COVID-19; President Trump signed the measure on March 6, 2020. Other countries have indicated they will also provide assistance. Congress also is considering other possible measures, including contingency plans for agencies to implement offsite telework for employees, financial assistance to the shale oil industry, paid sick leave, a reduction in the payroll tax,²⁴ and an extension of the tax filing deadline.²⁵ On March 11, 2020, President Trump announced a restriction on all travel from Europe to the United States for 30 days, directed the Small Business Administration (SBA) to offer low-interest loans to small businesses, and directed the Treasury Department to defer tax payments penalty-free for affected businesses.²⁶

On March 13, President Trump declared a state of emergency, freeing up disaster relief funding to assist state and local governments in addressing the effects of the virus. The President also announced additional testing for the virus, a website to help individuals identify symptoms of the virus, increased oil purchases for the Strategic Oil Reserve, and a waiver on interest payments on student loans.²⁷ The White House and House Democrats announced they had reached agreement on a package of measures that is intended to provide tens of billions of dollars for paid sick leave, unemployment insurance, food stamps, and other measures.²⁸

On March 17, 2020, President Trump announced that he intended to ask Congress for an additional \$1.2 trillion in funds to support the economy.²⁹ This amount reportedly would include loans to support cargo and passenger air carriers and loans and guarantees to other affected industries, loans to small businesses, and direct payments to individual taxpayers.³⁰ For additional information about the impact of COVID-19 on the U.S. economy see CRS Insight IN11235, *COVID-19: Potential Economic Effects*.³¹

³¹ CRS Insight IN11235, *COVID-19: Potential Economic Effects*, by Marc Labonte.

Europe

To date, European countries have not had the kind of synchronized policy response they developed during the global financial crisis of 2008-2009. Instead, they have used a combination of tax holidays for businesses and extensions of certain payments and loan guarantees and subsidies for workers. The European Commission announced that it was relaxing rules on government debt to allow countries more flexibility in using fiscal policies. The European Central Bank (ECB) announced that it was ready to take “appropriate and targeted measures,” if needed. With interest rates already low, however, it indicated that it could expand its program of providing loans to EU banks, or buying debt from EU firms, and possibly lowering its deposit rate further into negative territory in an attempt to shore up the Euro’s exchange rate.³² ECB President-designate Christine Lagarde called on EU leaders to take more urgent action to avoid the spread of coronavirus triggering a serious economic slowdown. The European Commission indicated that it was creating a nearly \$30 billion investment fund to address COVID-19 issues.³³ On March 12, 2020, the ECB decided to: (1) expand its longer-term refinance operations (LTRO) to provide low-cost loans to Eurozone banks to increase bank liquidity; (2) extend targeted longer-term refinance operations (TLTRO) to provide loans at below-market rates to businesses, especially small and medium-sized businesses, directly affected by COVID-19; (3) provide an additional €120 billion (about \$130 billion) for the Bank’s asset purchase program to provide liquidity to firms.³⁴ On March 13, 2020, financial market regulators in the UK, Italy, and Spain intervened in stock and bond markets to stabilize prices after historic swings in indexes on March 12, 2020.³⁵ In addition, the ECB announced that it would do more to assist financial markets in distress, including altering self-imposed rules on purchases of sovereign debt.³⁶ Germany’s Economic Minister announced on March 13, 2020, that Germany would provide unlimited loans to businesses experiencing negative economic activity (initially providing \$555 billion), tax breaks for businesses,³⁷ and export credits and guarantees.³⁸ Recent forecasts indicate that the economic effect of COVID-19 could push the Eurozone into an economic recession in 2020.³⁹

The United Kingdom

The Bank of England announced on March 11, 2020, that it would adopt a package of four measures to deal with any economic disruptions associated with COVID-19. The measures include: an unscheduled cut in the benchmark interest rate by 50 basis points (0.5%) to a historic low of 0.25%; reintroduce the Term Funding scheme for Small and Medium-sized Enterprises (TFSME) that provides banks with over \$110 billion for loans at low interest rates; lower banks' countercyclical capital buffer to zero percent, which is estimated to support over \$200 billion of bank lending to businesses; and freeze banks' dividend payments.⁴⁰ The UK Chancellor of the Exchequer proposed a national budget on March 11, 2020, that includes nearly \$35 billion in fiscal spending to counter adverse economic effects of the viral crisis and proposes that statutory sick leave be boosted by about \$2.5 billion in funds to small and medium businesses to provide up to 14 days of sick leave for affected employees. Part of the fiscal spending package includes open-ended funding for the National Health Service (NHS), \$6 billion in emergency funds to the NHS, \$600 million hardship fund to assist vulnerable people, and tax cuts and tax holidays for small businesses in certain affected sectors.⁴¹

Japan

The Bank of Japan, with already-low interest rates, interjected \$4.6 billion in liquidity into Japanese banks to provide short-term loans and twice that amount into exchange traded funds to aid Japanese businesses. The Japanese government also pledged to provide wage subsidies for parents forced to take time off due to school closures.⁴²

China

According to a recent CRS In Focus,⁴³ China's economic growth could go negative in the first quarter of 2020 and fall below 5% for the year, with more serious effects if the outbreak continues. In early February, China's central bank pumped \$57 billion into the banking system, capped banks' interest rates on loans for major firms, and extended deadlines for banks to curb shadow lending. The central bank has been setting the reference rate for China's currency stronger than its official close rate to keep it stable. On March 13, 2020, The People's Bank of China announced that it would provide \$78.8 billion in funding, primarily to small businesses, by reducing bank's reserve requirements.⁴⁴

The International Monetary Fund (IMF) is providing funding to poor and emerging market economies that are short on financial resources.⁴⁵ If the economic effects of the virus persist, countries may need to be proactive in coordinating fiscal and monetary policy responses, similar to actions taken by of the G-20 following the 2008-2009 global financial crisis.

MULTILATERAL RESPONSE

International Monetary Fund

The IMF announced that it is making available about \$50 billion for the global crisis response.⁴⁶ For low-income countries, the IMF is providing rapid-disbursing emergency financing of up to \$10 billion (50% of quota of eligible members) that can be accessed without a full-fledged IMF program. Other IMF members can access emergency financing through the Fund's Rapid Financing Instrument (RFI). This facility could provide about \$40 billion for emerging markets facing fiscal pressures from COVID-19. Separate from these resources, the IMF has a Catastrophe Containment and Relief Trust (CCRT), which provides eligible countries with up-front grants for relief on IMF debt service falling due. The CCRT was used during the 2014 Ebola outbreak, but is now underfunded, according to IMF Managing Director Kristolina Georgieva with just over \$200 million available against possible needs of over \$1 billion.⁴⁷ On March 11, 2020, the United Kingdom announced that it will contribute £150 million (about \$170 million) to the CCRT. To date, the United States has not contributed to the CCRT.⁴⁸

World Bank and Regional Development Banks

The World Bank announced that it is making up to \$12 billion in financing (\$8 billion of which is new) immediately available to help impacted developing countries.⁴⁹ This support comprises up to \$2.7 billion in new financing from the International Bank for Reconstruction and Development (IBRD), the World Bank's market-rate lending facility for middle-income developing countries and \$1.3 billion from the International Development Association (IDA), the World Bank's concessional facility for low-income countries. In addition, the Bank is reprioritizing \$2 billion of the Bank's existing portfolio. The International Finance Corporation (IFC), the Bank's private-sector lending arm is making available up to \$6 billion. According to the Bank, support will cover a wide range of activities including strengthening health services and primary health care, bolstering disease monitoring and reporting, training

front line health workers, encouraging community engagement to maintain public trust, and improving access to treatment for the poorest patients.

Several years ago, the World Bank introduced pandemic bonds, a novel form of catastrophe financing.⁵⁰ The Bank sold two classes of bonds worth \$320 million in a program designed to provide financing to developing countries facing an acute epidemic crisis if certain triggers are met. Once these conditions are met, bondholders no longer receive interest payments on their investments, the money is no longer repaid in full, and funds are used to support the particular crisis. In the case of COVID-19, for the bonds to be triggered, the epidemic must be continuing to grow 12 weeks after the first day of the outbreak. Critics have raised a range of concerns about the bonds, arguing that the terms are too restrictive and that the length of time needs to be shortened before triggering the bonds.⁵¹ Others stress that the proposal remains valid – shifting the cost of pandemic assistance from governments to the private sector, especially in light of the failure of past efforts to rally donor support to establish multilateral pandemic funds.

The Asian Development Bank (ADB) has approved a total of \$4 million to help developing countries in Asia and the Pacific.⁵² Of the total, \$2 million is for improving the immediate response capacity in Cambodia, China, Laos, Myanmar, Thailand, and Vietnam; \$2 million will be available to all ADB developing member countries in updating and implementing their pandemic response plans. The ADB also provided a private sector loan of up to \$18.6 million to Wuhan-based Jointown Pharmaceutical Group Co. Ltd. to enhance the distribution and supply of essential medicines and protective equipment.

International Economic Cooperation

On March 16, 2020, the leaders of the G-7 countries (Canada, France, Germany, Italy, Japan, the United Kingdom, and the United States) held an emergency summit by teleconference to discuss and coordinate their policy responses to the economic fallout from the global spread of COVID-19. In the joint statement released by the G-7 leaders after the emergency teleconference summit, the leaders stressed they are committed to doing “whatever is necessary to ensure a strong global response through closer cooperation and enhanced cooperation of efforts.”⁵³ The countries pledged to coordinate research efforts, increase the availability of medical equipment; mobilize “the full range” of policy instruments, including monetary and fiscal measures as well as targeted actions, to support workers, companies, and sectors most affected by the spread of COVID-19; task the finance ministers to coordinate on a weekly basis, and direct the IMF and the World Bank Group, as well as other international organizations, to support countries worldwide as part of a coordinated global response.⁵⁴

⁵⁰ Anna Gross, “Critics take aim at ‘failure’ of bond designed to fight disease,” *Financial Times*, March 10, 2020, <https://www.ft.com/content/a6239e12-5ec7-11ea-b0ab-339c2307bcd4>.

⁵³ White House, G-7 Leaders’ Statement, March 16, 2020, <https://www.whitehouse.gov/briefings-statements/g7-leaders-statement/>.

⁵⁴ Ibid.

News reports indicate that Saudi Arabia, the 2020 chair of the G-20, intends to call an emergency G-20 summit in coming days.⁵⁵ The G-20 is a broader group of economies, including the G-7 countries and several major emerging markets.⁵⁶ During the global financial crisis, world leaders decided that henceforth the G-20 would be the premiere forum for international economic cooperation. Some analysts have been surprised that the G-7 has been in front of the G-20 in responding to COVID-19, while other analysts have questioned whether the larger size and diversity of economies in the G-20 can make coordination more difficult.⁵⁷

Analysts are hopeful that the recent G-7 summit, and movement towards a G-20 summit, will mark a shift towards greater international cooperation at the highest (leader) levels in combatting the economic fallout from the spread of COVID-19.⁵⁸ An emergency of G-7 finance ministers on March 3, 2020, fell short of the aggressive and concrete coordinated action that investors and economists had been hoping for, and U.S. and European stock markets fell after the meeting.⁵⁹ More generally, governments have been divided over the appropriate response and in some cases have acted unilaterally, particularly when closing borders and imposing export restrictions on medical equipment and medicine. Meanwhile, international organizations including the IMF and multilateral development banks have tried to forge ahead with economic support given their current resources

ESTIMATED EFFECTS ON DEVELOPED AND MAJOR ECONOMIES

Among most developed and major developing economies, economic growth at the beginning of 2020 was tepid, but still was estimated to be positive. Countries highly dependent on trade—Canada, Germany, Italy, Japan, Mexico, and South Korea—and commodity exporters are now projected to be the most negatively affected by the slowdown in economic activity associated with the virus.⁶⁰ In addition, travel bans and quarantines are taking an especially heavy economic toll on China, South Korea, and Italy, where viral outbreaks have so far been most prevalent. The OECD notes that production declines in China have spillover effects around the world given China's role in producing computers, electronics, pharmaceuticals and transport equipment, and as a primary source of demand for many commodities.⁶¹

In early January 2020, before the coronavirus outbreak, economic growth in developing economies as a whole was projected by the International Monetary Fund (IMF) to be slightly more positive than in 2019. This outlook was based on progress being made in U.S.-China trade talks that were expected to roll back some tariffs and an increase in India's rate of growth. Growth rates in Latin America and the Middle East were also projected to be positive

⁵⁵ "Spain Says Saudi Arabia to Call G-20 to Meet on Coronavirus in Coming Days," *Reuters*, March 16, 2020.

⁵⁶ The G-20 includes the G-7 countries plus Argentina, Australia, Brazil, China, India, Indonesia, Mexico, Russia, Saudi Arabia, South Africa, South Korea, Turkey, and the European Union (EU).

⁵⁷ For more information about the G-20, see CRS Report R40977, *The G-20 and International Economic Cooperation: Background and Implications for Congress*, by Rebecca M. Nelson.

⁵⁸ See for example, Jennifer Rankin, "EU Leaders Divided on How to Protect Economies after Coronavirus," *The Guardian*, March 14, 2020.

⁶⁰ *OECD Interim Economic Assessment*, p. 7.

⁶¹ *Ibid.*, p. 5.

in 2020.⁶² These projections likely will be revised downward due to the slowdown in global trade associated with COVID-19, lower energy and commodity prices, and other secondary effects that could curtail growth. Commodity exporting countries, in particular, likely will experience a greater slowdown in growth than forecasted in earlier projections as a result of a slowdown on trade with China and lower commodity prices.

EMERGING MARKETS

The combined impact of COVID-19 and an oil price war between Saudi Arabia and Russia are hitting developing and emerging economies hard. Not all of these countries have the resources or policy flexibility to respond effectively. According to figures compiled by the Institute for International Finance (IIF), cumulative capital outflows from developing countries since January 2020 are double the level experienced during the 2008/2009 crisis and substantially higher than recent market events (Figure 1).⁶³

Source: Original graphic and data from International Institute for Finance using data from Haver. Edited by CRS for clarification.

Figure 1. Capital flows to emerging markets in global shocks.

The impact of the price war and lower energy demand associated with a COVID-19-related economic slowdown is especially hard on oil and gas exporters, some of whose currencies are at record lows (Figure 2). Oil importers, such as South Africa and Turkey, have also been hit hard; South Africa's rand has fallen 18%⁶⁴ against the dollar since the beginning of 2020 and the Turkish lira has lost 8.5%.⁶⁵

⁶² *Tentative Stabilization, Sluggish Recovery? World Economic Outlook Update*, January 20, 2020, The International Monetary Fund. <https://www.imf.org/en/Publications/WEO/Issues/2020/01/20/weo-update-january2020>.

⁶³ These include concerns in 2015 over China's renminbi devaluation and the so-called "Taper Tantrum" in 2013 when the Federal Reserve announced that it would slow down the pace of its post global financial crisis asset purchases. Sergei Lanau and Jonathan Fortun, "Economic Views –The COVID-19 Shock to EM Flows," Institute for International Finance, March 17, 2020.

⁶⁴ Paul Wallace, "Here's How the Oil Crash is Hitting Emerging Market Currencies," *Bloomberg*, March 17, 2020, <https://www.bloomberg.com/news/articles/2020-03-17/here-s-how-the-oil-crash-is-hitting-emerging-market-currencies>.

⁶⁵ Nevzat Devranoglu, "Turkish lira hits weakest level since 2018 currency crisis due to coronavirus," *Nasdaq*, March 17, 2020, <https://www.nasdaq.com/articles/turkish-lira-hits-weakest-level-since-2018-currency-crisis-due-to-coronavirus-2020-03-17>.

Depending on individual levels of foreign exchange reserves and the duration of the capital flow slowdown, some countries may have sufficient buffers to weather the slowdown, while others will likely need to make some form of current account adjustment (reduce spending, raise taxes, etc.). Several countries, such as Iran and Venezuela, have already asked the IMF for financial assistance and others are likely to follow.⁶⁶ (Venezuela's request was quickly rebuffed due to disagreement among the IMF membership over who is recognized as Venezuela's legitimate leader: Nicolás Maduro or Juan Guaidó.⁶⁷)

OTHER AFFECTED SECTORS

Public concerns over the spread of the virus have led to self-quarantines, reductions in airline and cruise liner travel, the closing of such institutions as the Louvre, and the rescheduling of theatrical releases of movies, including the sequel in the iconic James Bond series (titled, "No Time to Die").⁶⁸ School closures, so far in China, Japan, South Korea, Italy, India, and some U.S. States are affecting at least 290 million children worldwide, challenging parental leave policies.⁶⁹ Other countries are limiting the size of public gatherings.

Some businesses are considering new approaches to managing their workforces and work methods. These techniques build on, or in some places replace, such standard techniques as self-quarantines and travel bans. Some firms are adopting an open-leave policy to ensure employees receive sick pay if they are, or suspect they are, sick. Other firms are adopting paid sick leave policies to encourage sick employees to stay home and are adopting remote working policies.⁷⁰ Concerns remain, however, that some U.S. workers will continue going to work when they are sick, since not all U.S. employers provide paid sick leave. Microsoft and Amazon have instructed all of their Seattle-based employees to work from home until the end of March 2020.⁷¹

The drop in business and tourist travel is causing a sharp drop in scheduled airline flights by as much as 10%; airlines are estimating they could lose \$113 billion in 2020 (an estimate that could prove optimistic given the Trump Administration's announced restrictions on

⁶⁶ COVID-19-hit Iran asks IMF for aid amid US sanctions, *Deutsche Welle*, March 13, 2020, <https://www.dw.com/en/covid-19-hit-iran-asks-imf-for-aid-amid-us-sanctions/a-52763114>. Iran is currently under U.S. sanctions, which include, among other things, prohibitions on the ability of the United States to vote in favor of lending IMF or World Bank assistance to Iran. The United States, however, cannot unilaterally block lending to a particular country. Approving an IMF or World Bank loan requires a majority of the total voting power and the U.S. voting power is 16.5% of the total voting power at the IMF and 15.4% at the World Bank. Iran has not borrowed from the IMF since 1962, but did borrow from the World Bank between 2003 and 2005 over U.S. opposition.

Figure 2. Depreciation against the dollar since Jan. 1, 2020.

The decline in industrial activity has reduced demand for energy products such as crude oil, causing prices to drop sharply, which negatively affects energy producers, renewable energy producers, and electric vehicle manufacturers, but generally is positive for consumers and businesses. Saudi Arabia is pushing other OPEC (Organization of the Petroleum Exporting Countries) members collectively to reduce output by 1.5 million barrels a day to raise market prices. U.S. shale oil producers, who are not represented by OPEC, support the move to raise prices.⁷⁵ An unwillingness by Russia to agree to output reductions added to other downward pressures on oil prices and caused Saudi Arabia to engage in a price war with Russia that has driven oil prices below \$50 per barrel, the estimated break-even point for most oil producing countries.⁷⁶ In 2019, low energy prices combined with high debt levels reportedly caused U.S. energy producers to reduce their spending on capital equipment, reduced their profits and, in some cases, led to bankruptcies.⁷⁷ Reportedly, in late 2019 and early 2020, bond and equity investors, as well as banks, reduced their lending to shale oil producers and other energy producers that typically use oil and gas reserves as collateral.⁷⁸

Disruptions to industrial activity in China reportedly are causing delays in shipments of computers, cell phones, toys, and medical equipment.⁷⁹ Factory output in China, the United States, Japan, and South Korea all declined in the first months of 2020.⁸⁰ Reduced Chinese agricultural exports, including to Japan, are leading to shortages in some commodities. In addition, numerous auto producers are facing shortages in parts and other supplies that have been sourced in China. Reductions in international trade have also affected ocean freight prices. Some freight companies argue that they could be forced to shutter if prices do not rebound quickly.⁸¹ Disruptions in the movements of goods and people reportedly are causing some companies to reassess how international they want their supply chains to be.⁸² According to some estimates, nearly every member of the Fortune 1000 is being affected by disruptions in production in China.⁸³

CONCLUSION

The quickly evolving nature of the COVID-19 crisis creates a number of issues that make it difficult to estimate the full cost to global economic activity. These issues include, but are not limited to:

- How long will the crisis last?
- How many workers will be affected both temporarily and permanently?
- How many countries will be infected and how much economic activity will be reduced?
- When will the economic effects peak?
- How much economic activity will be lost as a result of the viral outbreak?
- What are the most effective monetary and fiscal policies at the national and global level to address the crisis?
- What temporary and permanent effects will the crisis have on how businesses organize their work forces?
- Many of the public health measures taken by Italy, Taiwan, South Korea, Hong Kong, China, etc. have sharply impacted their economies (plant closures, travel restrictions, etc.). How are the tradeoffs between public health and the economic impact of policies to contain the spread of the virus being weighed?

APPENDIX. SELECT MEASURES IMPLEMENTED OR ANNOUNCED BY MAJOR ECONOMIES IN RESPONSE TO COVID-19

United States	<i>U.S. Federal Reserve</i> March 3: Cut the target range for the federal funds rate by 0.5 percentage point. March 12: Expanded reverse repo operations, adding \$1.5 trillion of liquidity to the banking system. March 15: Cut the target range for the federal funds rate by a full percentage point to a range of 0.00% to 0.25% and restarted quantitative easing with the purchase of at least \$500 billion in Treasury securities and \$200 billion in mortgage-backed securities.
	<i>U.S. Congress</i> March 5: Passed, and the President signed, a bill providing \$8.3 billion in emergency funding for federal agencies to respond to the coronavirus outbreak (H.R. 6074: Coronavirus Preparedness and Response Supplemental Appropriations Act 2020). March 13: The House of Representatives passed a coronavirus response package (H.R. 6201: Families First Coronavirus Response Act). The Senate is expected to follow this week. <i>Trump Administration</i> March 13: President Trump declared a state of emergency, allowing the Federal Government to distribute up to \$50 billion in aid to states, cities, and territories. March 17: The Internal Revenue Service postponed the April 15 tax-payment deadline for 90 days and will waive interest and penalties. (The extension and waiver is available only to individuals and corporations that owe \$1 million or \$10 million or less, respectively.) March 17: Administration officials begin negotiations with Members of Congress on a third stimulus package of \$850 billion.
Australia	March 12: The government announced a AU\$17.6 billion (\$11.4 billion) stimulus package that includes support for business investment, cash flow assistance for small and medium sized business and employees, and household stimulus payments. March 16: The Australian Securities and Investments Commission ordered large equity market participants to reduce their number of executed trades by 25% from the levels executed on March 13, 2020, until further notice.
Canada	<i>Bank of Canada</i> March 13: Lowered its benchmark overnight rate to 1.25% from 1.75% in response to the epidemic.
	<i>Canadian Government</i> March 11: Unveiled CA\$1 billion (\$750 million) in funding for vaccine research and health measures. March 13: Announced CA\$10 billion (\$7.5 billion) credit package to help businesses, particularly small and medium-sized enterprises, struggling due to the pandemic.
Chile	March 16: The Central Bank of Chile cut its benchmark rate by 75 basis points to 1% on Monday and announced measures to inject liquidity, including allocating \$4 billion to purchase inflation-linked bank bonds and providing additional credit to banks.
China	<i>People's Bank of China (PBOC)</i> February 3: Expanded reverse repo operations by \$174 billion; added another \$71 billion on February 4. February 16: Cut the one-year medium-term lending facility rate by 10 basis points. February 20: Cut the one-year and five-year prime rates by 10 and 5 basis points, respectively. March 13: Lowered bank reserve requirements, freeing up about \$79 billion to be lent out.

	<i>PRC Government</i> February: Asked banks to extend the terms of business loans and commercial landlords to reduce rents. March: Earmarked \$15.9 billion to fight the epidemic.
Czech Republic	March 16: The Czech National Bank lowered its main two-week repo rate by 50 basis points to 1.75%, reversing its February rate hike to combat the hit from the virus outbreak. It also raised the number of repo operations that provide liquidity to banks to three times a week from once, noting that bids would be met with zero spread to the repo rate.
Egypt	<i>Central Bank of Egypt</i> March 16: Cut by 300 basis points both the overnight lending rate (from 13.25% to 10.25%) and the overnight deposit rate (from 12.25% to 9.25%) in what it described as a “preemptive” move to support the economy in the face of the COVID-19 outbreak. <i>Government of Egypt</i> March 14: The President indicated that the government will allocate 100 billion Egyptian pounds (\$6.4 billion) to finance a “comprehensive” state plan for combating the coronavirus outbreak.
European Union	<i>European Commission</i> March 11: Announced a 37 billion euro (\$41 billion) “Corona Investment Fund” that would use “spare” money from the EU budget to help businesses, health-care systems, and sectors in need; additionally, the EU’s own investment fund will guarantee 8 billion euros (\$8.9 billion) of loans to 100,000 small- and medium-sized enterprises and affected companies may be able to delay the payment of their existing loans. <i>European Central Bank (ECB)</i> March 12: Announced that it would provide banks with loans at a rate as low as minus 0.75%, below the -0.5% deposit rate, increase bond purchases by 120 billion euros (\$135.28 billion) this year (with a focus on corporate debt), and allow euro zone banks to fall short of some key capital and cash requirements (in order to keep credit flowing to the economy).
France	March 12: The government pledged more generous guarantees on loans made to small businesses, more cash for firms struggling to hold on to workers, and a solidarity fund to help companies cushion the blow from the coronavirus outbreak; it also announced that the government would be ready to increase funds available to help companies reduce workers’ hours, instead of laying them off. March 16: The president announced that the government would guarantee 300 billion euros in bank loans for small and medium-sized businesses. March 17: The Autorité des Marchés Financiers (AMF), France’s financial-markets authority, stated that it would forbid short selling of stock in 92 companies during the March 17 session. March 17: The government announced that it would spend 45 billion euros (\$50 billion) to help small businesses and employees struggling with the coronavirus outbreak, including through an expanded partial-unemployment package in which the state pays the salaries of employees who are not needed during the crisis.
Germany	March 13: Pledged to provide unlimited liquidity assistance to German companies hit by the pandemic. (The measure envisages a massive expansion of loans provided by KfW, the state development bank, and will allow companies to defer billions of euros in tax payments.) The Bundestag also expanded the <i>Kurzarbeit</i> or short-time work scheme, under which companies that put their workers on reduced hours can receive state support. The government also indicated that it would boost investments by €3.1 billion per year between 2021 and 2024.
Hong Kong	February 26: The government announced a HK\$120 billion (\$15.4 billion) relief package as part of its 2020–2021 budget, including a payment of HK\$10,000 (\$1,200) to each permanent resident of the city 18 or older, paying one month’s rent for people living in public housing, cutting payroll, income, property, and business taxes, low-interest, government-guaranteed loans for businesses, and an extra month’s worth of payments to people collecting old-age or disability benefits

India	<i>Reserve Bank of India</i> March 12: Announced a \$2 billion injection into the foreign-exchange market to support the rupee. March 13: Announced a plan to add liquidity through short-term repurchase operations. <i>Government of India</i> March 15: Pledged \$10 million towards South Asian Association for Regional Cooperation (SAARC) “coronavirus emergency fund.” March 11: The government announced two packages worth 25 billion euros (\$28.3 billion): A package worth 12 billion euros will provide extra funding for the health system as well as a mix of measures to help companies and households, including freezing tax and loan payments and boosting unemployment benefits to ensure no jobs were lost. The remainder will be a reserve to pay for any further measures. The government also indicated that payments on mortgages will be suspended across Italy. ABI, Italy’s banking lobby, said lenders would offer debt moratoriums to small firms and households grappling with the economic fallout from the virus.
Italy	
Japan	<i>Bank of Japan</i> March 16: Announced that it would (1) double its upper limit of annual purchases of exchange traded funds to 12 trillion yen (\$112.46 billion) and of real-estate investment trusts to 180 billion yen (\$1.7 billion) per year, (2) expand its upper limit of its corporate bond balance and commercial paper balance by 1 trillion yen (\$9.5 billion) each, and (3) start a lending program for commercial banks, providing them with one-year loans in exchange for corporate collateral worth 8 trillion yen (\$75.6 billion). <i>Japanese Government</i> February 13: Unveiled a set of measures worth 15.3 billion yen (\$140 million) to fight the spread of coronavirus; secured 500 billion yen (\$4.7 billion) for emergency lending and loan guarantees at the Japan Finance Corporation and other institutions for small businesses hit hard by the virus outbreak. March 10: Unveiled a second package of measures totaling 430.8 billion yen (\$4.1 billion) in spending to cope with the fallout of the coronavirus outbreak (focusing on support to small and mid-sized firms) and boosted to 1.6 trillion yen (\$15.1 billion) its special financing for small- and mid-size firms hit by the virus, up from 500 billion yen. March 16: The Central Bank of Kuwait cut by 100 basis points its deposit rate to 1.5% and its overnight, one-week, and one-month repo rates to 1%, 1.25%, and 1.75%, respectively.
Kuwait	
Mexico	February 13: The Bank of Mexico cut its key rate by 25 basis points to 7.0%. <i>Government of New Zealand</i> March 16: Announced a spending package of NZ\$12.1 billion (\$7.3 billion), equivalent to 4% of GDP in an attempt to fight the effects of COVID-19 on the economy; approximately NZ\$5 billion will go toward wage subsidies for businesses, NZ\$2.8 billion toward income support, NZ\$2.8 billion in business tax relief, and NZ\$600 million toward the airline industry. <i>Reserve Bank of New Zealand</i> March 16: Cut the official cash rate by 75 basis points to a record low of 0.25%, and pledged to keep it at this level for at least 12 months.
New Zealand	
Norway	March 13: The Norges Bank, Norway’s central bank, cut its key interest rate to 1% from 1.5%, as it seeks to counter the economic impact of the coronavirus pandemic. It indicated that it would offer funding to banks to help counter the volatility in financial markets and announced that banks’ countercyclical capital buffer would be reduced from 2.5% to 1%, to help banks continue to lend money.
Philippines	March 13: The government instructed the Government Service Insurance System and the Social Security System “to take advantage of the low stock prices” and “support the stock market by at least doubling their daily average purchase volumes” from 2019. March 17: The Philippine Stock Exchange halted all stock, bond and currency trading until further notice, after President Rodrigo Duterte placed Luzon, the country’s economic powerhouse, under “enhanced community quarantine”.

Qatar	<i>Qatar Central Bank</i> March 16: Cut the deposit rate by 50 basis points to 1%, lending rate by 100 basis points to 2.50%, and repurchase rate (repo) by 50 basis points to 1%.	<i>Government of Qatar</i> March 15: The Emir of Qatar announced several measures to shield the economic and financial sectors in the country from the impact of the coronavirus, including: (1) allocating 75 billion Qatari riyals (\$20.6 billion) to support and provide financial and economic incentives in the private sector, (2) directing the Central Bank of Qatar to provide additional liquidity to banks operating in the country and putting in place the appropriate mechanism to encourage banks to postpone loan installments and obligations of the private sector with a grace period of six months, (3) directing the Qatar Development Bank to postpone the installments for all borrowers for a period of six months, (4) directing the government to increase its investments in the stock exchange by 10 billion Qatari riyals (\$2.75 billion), (5) exempting food and medical goods from customs duties for a period of six months, and (6) exempting the various sectors of the economy from electricity and water fees for a period of 6 months.
	Saudi Arabia	March 15: The Saudi Arabian Monetary Authority announced that it had prepared a 50 billion riyal (\$13.32 billion) package to help small and medium-sized enterprises cope with the economic impacts of coronavirus; it also lowered by 75 basis points both its repo rate to 1% and its reverse repo rate to 0.5%.
Singapore	February 18: The government announced around \$4.5 billion in financial packages to help contain the coronavirus outbreak, including \$575 million to fight and contain the disease, mainly through healthcare funding, and 4 billion in economic stimulus measures to manage its impact on businesses, jobs and households.	
South Korea	March 3: Announced a 11.7 trillion won (\$9.8 billion) stimulus package that includes funding for medical institutions and quarantine efforts, assistance to small- to medium-sized businesses struggling to pay wages to their workers, and subsidies for child care.	
Spain	March 12: The government announced additional support for the health system and a 14 billion euro (\$15.6 billion) stimulus package for the economy.	
Sri Lanka	March 16: The Central Bank of Sri Lanka cut the Standing Deposit Facility Rate (SDFR) and the Standing Lending Facility Rate (SLFR) by 25 basis points to 6.25% and 7.25%, respectively, and the Statutory Reserve Ratio (SRR) on all rupee deposit liabilities of licensed commercial banks was reduced by 1 percentage point to 4% March 16: The Colombo Stock Exchange was closed until March 19, as the government extended the public holiday in a bid to halt the spread of coronavirus in the country.	
Sweden	<i>Sveriges Riksbank</i> March 13: Stated that it would lend up to 500 billion crowns (\$51 billion) to Swedish companies via banks to shore up credit flows as the epidemic wreaks havoc on financial markets. March 16: Announced that it would buy securities for up to an additional 300 billion Swedish crowns (\$31 billion) in 2020 to facilitate credit supply and mitigate the downturn in the economy caused by the coronavirus, reduced the overnight lending rate to banks to 0.2 percentage point above its repo rate (from 0.75 percentage point), and indicated that it would be flexible with the collateral banks can use when they borrow money from the Riksbank, giving lenders more scope to use mortgage bonds as collateral.	
	<i>Government of Sweden</i> March 16: Presented a package worth more than 300 billion Swedish crowns (\$31 billion) to support the economy in the face of the coronavirus pandemic. It included measures such as the central government assuming the full cost for sick leave from companies through the months of April and May 2020 and for temporary redundancies due to the crisis, and allowing companies to put off paying tax and VAT for up to a year (retroactive to the start of 2020).	

Taiwan	February 25: The government approved a T\$60 billion (\$2 billion) package to help cushion the impact of the coronavirus outbreak on its export-reliant economy, including loans for small businesses, subsidies for hard-hit tour agencies, tax cuts for tour bus drivers, and vouchers to spend on food in night markets. March 12: The president announced that an additional T\$40 billion (\$1.33 billion) from the Employment Stabilization Fund and the Tourism Development Fund would be available to stimulate Taiwanese economy. March 15: The Central Bank of the UAE announced a 100 billion dirham (\$27 billion) stimulus package to deal with the economic effects of the coronavirus pandemic; it cut the rate on one-week certificates of deposit by 75 basis points and will also ease regulatory limits on loans.
United Arab Emirates (UAE)	
United Kingdom	<i>Bank of England</i> March 11: Cut its benchmark interest rate by half a percentage point, to 0.25%, revived a program to support lending to small and midsize businesses, and reduced bank capital requirements to further boost credit. <i>UK Government</i> March 11: Announced a stimulus package totaling 30 billion pounds (\$39 billion). It will include 7 billion pounds (\$8.6 billion) available to support the labor market, 5 billion pounds (\$6.1 billion) to help the health-care system, and 18 billion pounds (\$22 billion) to support the UK economy, bringing the total fiscal stimulus to 30 billion pounds (\$39 billion). (Among the specific measures, there will be a tax cut for retailers, cash grants to small businesses, a mandate to provide sick pay for people who need to self-isolate, subsidies to cover the costs of sick pay for small businesses, and expanded access to government benefits for the self-employed and unemployed.)
Vietnam	March 16: The State Bank of Vietnam cut by 100 basis points both its refinance rate (to 5%) and the overnight lending rate in the inter-bank market (to 6%), and by 50 basis points its discount rate (to 3.5%).

Chapter 385

COVID-19: POTENTIAL ECONOMIC EFFECTS*

Marc Labonte

ABSTRACT

This Insight discusses the potential economic effects of the coronavirus (COVID-19) on the U.S. economy. For background on the coronavirus, see CRS In Focus IF11421, *COVID-19: Global Implications and Responses*, by Sara M. Tharakan et al.

CHANNELS THROUGH WHICH THE VIRUS COULD AFFECT THE ECONOMY

Although the COVID-19 outbreak presently is most widespread abroad, it will directly affect foreign demand for U.S. exports of goods and services. As discussed in this CRS In Focus, the coronavirus could also disrupt U.S. companies' international supply chains. If COVID-19 becomes widespread in the United States, it could directly reduce domestic economic activity by reducing both supply and demand. On the supply side, hours worked would be reduced by illnesses and fatalities and any work stoppages to prevent the virus from spreading. On the demand side, spending could be reduced by quarantines and other attempts to avoid crowds, such as public event cancellations. In addition, fear and uncertainty could reduce business and consumer confidence, leading to a reduction in spending. A reduction in investor confidence could also tighten financial conditions. For example, the sharp decline in the stock market since late February 2020 was widely perceived to be in response to worsening news about the virus. In general, these macroeconomic effects would be expected to eventually reverse once conditions return to normal, except to the extent COVID-19 causes worker fatalities.

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. IN11235, dated March 11, 2020.

UNKNOWNNS IN EVALUATING THE ECONOMIC IMPACT

How large could the economic effects of the coronavirus ultimately be? At this stage, uncertainty is so great that a very wide range of economic outcomes—from little effect on the U.S. economy to a severe downturn—is plausible. The unknowns include the following questions:

- How many people will become infected over the course of the outbreak in the United States and abroad?
- How long will the outbreak last?
- What public and private measures will ultimately be taken that disrupt normal economic activity (e.g., travel restrictions, closures, shutdowns, cancellations)?
- How easily can businesses find substitutes for supply chain disruptions?
- How many businesses will fail before the outbreak ends?
- How will consumer and investor confidence be affected?
- What fiscal or monetary policy actions will ultimately be taken to offset the economic effects, and how effective would they be in a pandemic? To date, an emergency supplemental appropriation has been enacted (P.L. 116-123), and the Federal Reserve has reduced interest rates by 0.5 percentage points.

ECONOMIC ESTIMATES

Two recent studies attempt to quantify the potential economic effects of the outbreak. The purpose of these studies is to illustrate how the economy would be affected under different outbreak scenarios rather than to provide the best projection of the outbreak's scope.

OECD

In its base-case scenario—a contained outbreak centered in China—the Organisation for Economic Co-operation and Development (OECD) stated “global GDP growth is projected to slow from 2.9% in 2019 to 2.4% this year, before picking up to around 3¼ per cent in 2021 as the effects of the coronavirus fade and output gradually recovers.” In this scenario, U.S. growth is only 0.1 percentage points lower in 2020 and is 0.1 percentage points higher in 2021. Despite the negative impact of COVID- 19, the OECD projects a global recession is averted as growth remains positive in all the major economies—including China—except Italy. The base-case scenario assumes the outbreak peaks in the first quarter of 2020 and gradually fades thereafter. (The OECD did not report specific estimates on the number of illnesses or fatalities.) The base-case scenario also incorporates an assumption that monetary stimulus is used around the world to offset the negative effects.

Source: Organization for Economic Co-operation and Development (OECD).

Notes: *For the domino scenario, “U.S.” is for North America.

Figure 1. Projected decline in 2020 GDP growth under two scenarios OECD.

The OECD also presents a “domino scenario” where the virus “spread much more intensively ... through the wider Asia-Pacific region and the major advanced economies in the northern hemisphere.” In this scenario, “the level of world GDP is reduced by up to 1¾ per cent (relative to baseline) at the peak of the shock in the latter half of 2020, with the full year impact on global GDP growth in 2020 being close to 1½ per cent.” The OECD does not present an estimate for the effect on U.S. growth in the domino scenario, but growth in North America would decline by 1.5 percentage points. Figure 1 illustrates both scenarios presented by the OECD.

McKibbin and Fernando

A Brookings Institution working paper by Warwick McKibbin and Roshen Fernando used a long-standing economic forecasting model developed by one of the authors to simulate economic effects under seven different outbreak scenarios—three that limit the outbreak to China and four in which the outbreak is worldwide. (The paper does not provide the relative likelihood of the various scenarios.) The model projects that “even a low-end pandemic modeled on the Hong Kong Flu is expected to reduce global GDP by around \$2.4 trillion and a more serious outbreak similar to the Spanish flu reduces global GDP by over \$9 trillion in 2020.” The loss in U.S. GDP relative to the 2020 baseline varies between 0.1%-8.4% across the scenarios. The scenarios assume a decline in the labor supply of 0.1%-3.44% in China and 0%-1.3% in the United States.

**Table 1. Projected decrease in 2020 GDP under various scenarios
McKibbin and Fernando**

Decrease in 2020 GDP Relative to Baseline			
Scenario	COVID-19 Deaths	United States	China
Scenario 1	China: 279	-0.1	-0.4
Scenario 2	China: 3,493	-0.1	-1.9
Scenario 3	China: 12,573	-0.2	-6.0
Scenario 4	China: 2,794; U.S.: 236	-2.0	-1.6
Scenario 5	China: 6,985; U.S.: 589	-4.8	-3.6
Scenario 6	China: 12,573; U.S.: 1,060	-8.4	-6.2
Scenario 7	China: 2,794; U.S.: 236	-1.5	-2.2

Source: McKibbin and Fernando.

Notes: In Scenarios 1-3, the mortality rate for the rest of the world is negligible. In Scenario 7, the outbreak recurs annually; in the other scenarios, it is a one-time outbreak.

U.S. and global growth had been projected to be moderate before the outbreak. Therefore, the economic effects of COVID-19 could result in a growth slowdown but would have to be large for the economy to contract, as the forecasts above illustrate. The estimated effects presented above are for the whole year; it is expected, however, that the economic effects will be larger in the first half of the year.

Chapter 386

DOMESTIC PUBLIC HEALTH RESPONSE TO COVID-19: CURRENT STATUS AND RESOURCES GUIDE*

Kavya Sekar and Ada S. Cornell

ABSTRACT

The global outbreak of Coronavirus Disease 2019, COVID-19, is affecting communities throughout the United States, with case counts growing daily. Containment and mitigation efforts by federal, state, and local governments have been undertaken to “flatten the curve”—that is, to curb widespread transmission that could overwhelm the nation’s health care system.

This CRS Insight presents selected international and U.S. government actions and related events, CRS products, and federal websites relevant to the *domestic public health response* to COVID-19. As the situation evolves, CRS will continue to publish and update products relevant to the current needs of Congress. This Insight will be updated accordingly.

This Insight does not provide information on the international response to COVID-19, nor on economic or other non-health policy issues related to COVID-19. This Insight also does not address issues related to health insurance and financing. For further information on those issues, see the CRS Coronavirus Disease 2019 homepage.

A Snapshot of the Domestic Public Health Response to COVID-19, as of March 18, 2020

Note: All dates below are in 2020.

International Events and World Health Organization (WHO) Actions

<https://www.who.int/emergencies/diseases/novel-coronavirus-2019>

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. IN11253, dated March 18, 2020.

- WHO declared the COVID-19 outbreak to be a Public Health Emergency of International Concern (PHEIC) on January 30.
- WHO announced the official name for the disease, COVID-19, on February 11.
- WHO raised its global risk assessment for the outbreak to “very high,” its highest risk level, on February 28.
- WHO declared the global COVID-19 outbreak a “pandemic” on March 11.
- Globally, over 200,000 cases have been confirmed in over 150 countries, with over 8,500 deaths reported.

United States Actions and Status

<https://www.hhs.gov/about/news/index.html>;

<https://www.cdc.gov/coronavirus/COVID-19/summary.html>; and

<https://www.fda.gov/emergency-preparedness-and-response/mcm-issues/novel-coronavirus->
COVID-19.

- Several emergency declarations are in effect, including a Public Health Emergency under Section 319 of the Public Health Service Act; an Emergency Declaration pursuant to Section 501(b) of the Stafford Act; and a National Emergency declaration pursuant to the National Emergencies Act. Waivers are in effect under Section 1135 of the Social Security Act to aid the health care system with surge capacity.
- President Donald Trump announced the formation of the President’s Coronavirus Task Force, and appointed Vice President Mike Pence as the coordinator and Dr. Deborah Brix as response coordinator.
- Congress and the President enacted the Coronavirus Preparedness and Response Supplemental Appropriations Act (P.L. 116-123) on March 6, which provides a total of \$7.767 billion in appropriations: \$6.497 billion for HHS (including contingent amount), \$20 million for the Small Business Administration, and \$1.250 billion for foreign operations. Expanded telehealth services in Division B of the act additionally have a cost estimate of \$490 million over the course of FY2020 through FY2022. Prior to enactment, health response efforts were primarily supported by the Centers for Disease Control and Prevention (CDC) Infectious Diseases Rapid Response Reserve Fund allotment of \$105 million and HHS transfers of \$136 million.
- The House and Senate passed The Families First Coronavirus Response Act, H.R. 6201, which includes several provisions related to health care coverage and delivery. Discussions about additional measures to provide response assistance are underway.
- CDC has developed a diagnostic test kit for the virus and distributed it to public health laboratories pursuant to an Emergency Use Authorization (EUA) issued by the U.S. Food and Drug Administration (FDA) on February 4. Issues with test performance have limited access to testing at a local level. FDA has issued several EUAs for COVID-19 diagnostic tests (including for both commercial test kits and laboratory-developed tests, or LDTs) and personal protective equipment.
- FDA issued guidance on February 29 to authorize certain CLIA (Clinical Laboratory Improvement Amendments) certified labs to validate and use their own COVID-19 laboratory-developed tests for clinical diagnosis before EUA is granted. On March 16, FDA expanded this policy to cover the manufacture, distribution and use of commercial test kits prior to EUA authorization. In this guidance, FDA also authorizes states to further authorize laboratories within their own state to develop and perform tests for COVID-19 pursuant to state law and without the objection of the FDA.
- Medical countermeasures (diagnostics, vaccines, and therapeutics) are in development, including those supported by the National Institutes of Health (NIH) and the Biomedical Advanced Research and Development Authority (BARDA). An NIH-supported Moderna vaccine is in Phase 1 clinical trials (early-stage testing in humans). Gilead’s Remdesivir antiviral therapy is in Phase 3 clinical

trials and available under expanded access (also known as compassionate use). Widespread availability of a vaccine is projected to be at least a year away, while initial results of clinical trials of potential treatments are said to be expected by May.

- Travel restrictions and quarantine requirements are in effect for certain travelers who have been in mainland China, the Islamic Republic of Iran, Schengen area of the European Union, the United Kingdom and the Republic of Ireland within 14 days prior to arrival, pursuant to proclamations issued by President Trump.
- Enhanced health screenings are in place at 13 major U.S. airports. Health screenings and referrals are in place at all air, land, and sea ports of entry by DHS.
- CDC has issued guidance for the general public, schools, health care providers, health departments, pregnant women and children, travelers, and others.
- Containment and mitigation efforts are underway in several state and local jurisdictions. Several states have mandated cancellation of events, closures of schools, bars, and/or restaurants, among other actions. Several counties in Northern California are under a shelter-in-place order.
- The White House has advised Americans to avoid gatherings of 10 or more people, discretionary travel, and restaurants, food courts, and bars.
- Over 7,500 cases have been reported in 50 states, the District of Columbia, Puerto Rico, Guam, and the U.S. Virgin Islands, with over 100 deaths reported. Given limitations with testing, these are likely to be underestimates of disease spread.

Chapter 387

COVID-19 MEDICAL COUNTERMEASURES: INTELLECTUAL PROPERTY AND AFFORDABILITY*

Kevin J. Hickey

ABSTRACT

Federal agencies and private industry have begun efforts to develop and test medical countermeasures (such as antiviral treatments and vaccines) to combat COVID-19, the disease caused by the novel coronavirus SARS-CoV-2. For example, Gilead Sciences has begun clinical trials, both in China and in the United States, to test whether its experimental antiviral drug remdesivir is safe and effective against COVID-19. In February 2020, the Biomedical Advanced Research and Development Authority (BARDA), a division of the Department of Health and Human Services (HHS), entered into agreements with two pharmaceutical companies—Johnson & Johnson and Sanofi—to develop vaccines for COVID-19. BARDA has also partnered with Regeneron Pharmaceuticals to develop a monoclonal antibody treatment for COVID-19. (See this CRS report for further detail on these and other potential countermeasures against COVID-19.)

Some Members of Congress have raised concerns about whether these medical countermeasures, if shown to be safe and effective, will be affordable and accessible to the public—especially if federal funds contribute to their development. The Coronavirus Preparedness and Response Supplemental Appropriations Act (CPRSA), enacted into law on March 6, 2020, contains two provisions relating to affordability of COVID-19 countermeasures. First, products purchased by the federal government using funds appropriated by CPRSA, including vaccines, therapeutics, and diagnostics for COVID-19, “shall be purchased in accordance with Federal Acquisition Regulation guidance on fair and reasonable pricing.”

Second, CPRSA states that the Secretary of HHS “may take such measures authorized under current law to ensure that vaccines, therapeutics, and diagnostics developed from funds provided in this Act will be affordable in the commercial market.”

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. LSB10422, dated March 18, 2020.

This Sidebar reviews several intellectual property (IP) rights provisions under current law that the federal government could use to try to ensure that COVID-19 countermeasures are accessible and affordable. Other actions that the federal government might hypothetically take—such as additional spending, production by federal agencies, governmental negotiation, or direct price controls—are beyond the scope of this Sidebar, in that such measures do not implicate IP rights and may require additional legislative action beyond the “current law” referenced in CPRSA.

PATENT RIGHTS IN INVENTIONS MADE WITH FEDERAL ASSISTANCE

Patent Basics

Under the Patent Act, any person who “invents or discovers any new and useful process, machine, manufacture, or composition of matter” may apply for a patent on the invention with the U.S. Patent and Trademark Office (PTO). PTO patent examiners evaluate the application to ensure it meets all the applicable legal requirements to merit the grant of a patent. If the patent examiner concludes that the claimed invention is new, nonobvious, useful, directed at patentable subject matter, and adequately disclosed and claimed, PTO will issue the patent. If granted, patents typically expire twenty years after the initial patent application is filed.

Patents are available for almost every field of technology, including biotechnology, chemistry, computer hardware, electrical engineering, mechanical engineering, and manufacturing processes. In the pharmaceutical context, if an inventor is the first to synthesize a particular chemical that is useful in treating disease, she may seek a patent claiming the chemical itself. That said, patents on a pharmaceutical’s active ingredient are only a subset of patents relating to pharmaceuticals and other medical treatments. Particular drug formulations, methods of using the pharmaceutical to treat a particular disease, methods and technologies to administer a pharmaceutical, methods and technologies to manufacture a pharmaceutical, as well as methods and technologies for testing for and diagnosing disease, are all patentable if they meet Patent Act’s requirements.

To encourage innovation, a valid patent holder has the exclusive right to make, use, sell, and import (collectively, “practice”) the patented invention in the United States. Patents are thus said to confer a “temporary monopoly” on the patent holder: anyone else who wishes to practice the invention needs to obtain permission from the patent holder to do so (and, typically, pays for that permission). In some situations, patent rights can confer substantial market power on patent holders, enabling them to charge higher-than-competitive prices for the patented product, as a monopolist would. Some empirical studies have found patent rights are among the most important factors driving high prices for pharmaceuticals. At least to some extent, higher prices are part of the patent system’s design, in that they enable inventors to recoup the costs of research and development necessary to produce the invention in the first place. Fundamentally, IP law seeks to balance the importance of providing incentives to innovate against the costs that IP rights impose on the public in the form of higher prices and reduced competition.

Inventions Made with Federal Assistance

Patent rights initially vest in the individual inventor or inventors, as a general rule. Commonly, however, employees agree by contract to assign their patent rights to inventions made in the course of their employment to their employer, who may seek a patent on an employee's behalf.

When private parties rely on federal assistance to develop an invention, any resulting patent rights will typically be owned by either the U.S. government or the federal contractor, depending on the nature of federal involvement. For inventions made by federal employees during their official duties, the federal government will typically obtain title to the patent. The federal government's general policy for federally owned inventions, under the Stevenson-Wydler Technology Innovation Act and the Federal Technology Transfer Act of 1986, is to encourage their commercialization by licensing the federally owned patent rights to private parties—a process called “technology transfer.” Under technology transfer agreements, federal agencies grant private parties the exclusive or nonexclusive right to practice the invention, while the U.S. government retains: (1) a “nontransferable, irrevocable, paid-up license . . . to practice the invention or . . . by or on behalf of” the United States (the “government-use license”); and (2) the power “to terminate the license in whole or in part” based on grounds similar to the conditions for “march-in rights” (discussed below).

The Bayh-Dole Act of 1980 (Bayh-Dole), as amended, applies to inventions that a federal contractor conceives or first reduces to practice during the performance of a funding agreement with a federal agency. Under Bayh-Dole, the federal contractor may elect to retain the patent rights for a federally funded invention. In exchange, however, the contractor provides the federal agency with a government-use license, and the United States retains the authority to grant compulsory licenses to third parties in certain circumstances (“march-in rights”). Although Bayh-Dole, by its terms, only applies to federal contractors that are nonprofit organizations or small businesses, longstanding executive practice (codified by regulation) has applied Bayh-Dole to all federal contractors, regardless of size.

Finally, federal laboratories and private parties may enter into cooperative research and development agreements (CRADAs) in which both parties agree to provide services, facilities, equipment, IP, or other resources, but the federal government does not provide federal funding to the non-federal party. In this situation, ownership of IP rights may depend on the terms of the agreement. However, the federal laboratory generally has the authority to license existing federally owned IP to a private party as part of a CRADA, as well as to license or assign inventions made in whole or part by a federal employee working under a CRADA. In return, the federal government retains a government-use license and compulsory-licensing authority similar to Bayh-Dole march-in rights.

These general rules for patent ownership are subject to various exceptions and waivers, depending on the agency and circumstances. For example, some agencies (including BARDA and the National Institutes of Health) have the authority to enter into transactions that are *not* contracts, grants, or cooperative agreements, known as “other transaction” authority. “Other transactions” are exempt from many statutory provisions and procurement regulations, including Bayh-Dole's requirements. BARDA's template for other transactions includes contractual patent provisions much like those of Bayh-Dole, including march-in rights provisions. These patent provisions are “fluid and negotiable,” however, and may be different

for particular transactions. In addition, both Stevenson-Wydler's and Bayh-Dole's requirements contain specific exceptions. For example, Bayh-Dole's patent provisions do not apply to contractors located outside the United States, nor in "exceptional circumstances," including if necessary "to meet the needs of the Government and protect the public against nonuse or unreasonable use of inventions."

GOVERNMENTAL COMPULSORY PATENT LICENSES

As explained above, a patent holder generally has the exclusive right to make, use, sell, and import an invention. Thus, any other person who wishes to practice that invention will ordinarily need a license (i.e., permission) from the patent holder, or else be exposed to legal liability. In certain cases, however, patents may be subject to a "compulsory license," which allows another person to practice the invention *without* the consent of the patent holder. Compulsory licenses require the sanction of a governmental entity and the payment of compensation to the patent holder. Compulsory licenses differ from ordinary licenses in two important respects. First, the person seeking to use the invention need not obtain permission from the patent holder. Second, the compensation paid to the patent holder is determined by operation of law, not by private contractual negotiations between the licensee and the patent holder.

March-in Rights under the Bayh-Dole Act (35 U.S.C. 203)

Although Bayh-Dole generally allows federal contractors to take title to patents on inventions created with federal funding, the federal government retains the authority to "march in" and grant compulsory licenses to third parties in some circumstances. Specifically, the federal agency that provided the funding may require the federal contractor to grant a patent license to a third party if the agency determines that either:

- 1) action is necessary because the contractor or assignee has not taken, or is not expected to take within a reasonable time, effective steps to achieve practical application of the subject invention in such field of use;
- 2) action is *necessary to alleviate health or safety needs* which are not reasonably satisfied by the contractor, assignee, or their licensees;
- 3) action is necessary to meet requirements for public use specified by Federal regulations and such requirements are not reasonably satisfied by the contractor, assignee, or licensees; or
- 4) action is necessary because the agreement [to prefer U.S. manufacturing of the invention by any of the contractor's exclusive licensees] has not been obtained or waived or because a licensee of the exclusive right to use or sell any subject invention in the United States is in breach of its agreement [to prefer U.S. manufacturing].

A license granted under Bayh-Dole's march-in provisions must be "upon terms that are reasonable under the circumstances," which may require that the licensee pay compensation to the patent holder (i.e., the federal contractor or its assignee).

The federal government has never exercised march-in rights under Bayh-Dole. Advocacy groups have petitioned the National Institute of Health (NIH) several times to exercise march-in rights based on the high prices of certain drugs developed with federal funding, such as treatments for HIV/AIDS. NIH has rejected these petitions, contending that pricing concerns alone are insufficient to exercise march-in rights—so long as the invention is on the market and available to patients. In the context of a pandemic like COVID-19, the "health or safety needs" language would appear to provide a possible basis for the exercise of march-in rights, should the federal agency determine that compulsory licensing is necessary to address public health needs unmet by a federal contractor.

Governmental Use Rights (28 U.S.C. § 1498)

A broader statutory authority than march-in rights, 28 U.S.C. § 1498 (section 1498), applies to any patented invention—not just inventions made with federal funding. Under section 1498, sometimes described as an "eminent domain" provision for patents, the U.S. government has the authority to use or manufacture any patented invention "without license." In practice, this means that if the U.S. government determines that it needs to practice an invention, it need not ask permission from the patent holder to do so, and—despite the existence of the patent—courts will not order the government to cease infringing activity. The patent holder, however, has the right to sue in the U.S. Court of Federal Claims for "reasonable and entire compensation" for the government's use of the patented invention. In effect, then, section 1498 allows the United States to issue itself a compulsory license to make and use any patented invention without obtaining the permission of the patent holder, in exchange for consenting to liability in a suit seeking reasonable compensation for the government's use.

In the context of COVID-19 medical countermeasures, the U.S. government could rely on section 1498 to make and use any patented invention without the consent of the patent holder. Because section 1498 extends to infringement "by a contractor, a subcontractor, or any person, firm, or corporation for the [U.S.] Government and with the authorization or consent of the [U.S.] Government," the federal government could also extend its section 1498 authority to the actions of private entities by authorizing them to practice a patented invention on behalf of the government.

TARGETED LEGISLATION AND THE TAKINGS CLAUSE

U.S. patent rights were created by an act of Congress. Thus, should patent rights inhibit access to or affordability of COVID-19 countermeasures and should Congress conclude that existing legal authorities are insufficient, targeted legislation is a possible option. Although the U.S. Constitution grants Congress the authority to create a patent system, it does not require Congress to do so. Congress therefore has wide discretion in designing the patent

system's scope and operation. So long as it operates prospectively (and consistent with its international treaty obligations), Congress may exclude certain technologies from patent protection. For example, a provision in the 2011 Leahy-Smith America Invents Act prohibits the PTO from issuing a patent on inventions "directed to or encompassing a human organism."

When legislation operates retroactively to invalidate a patent or diminish patent rights, however, it raises issues under the Takings Clause of the Fifth Amendment to the U.S. Constitution. The Takings Clause states that if "private property [is] taken for public use" by the U.S. government, it must provide "just compensation." The Supreme Court has suggested several times that patents are private property under the Takings Clause, but it has never held so explicitly. Presuming that patents are private property under the Fifth Amendment, legislation that retroactively impairs patent rights could give rise to a constitutional claim for just compensation. Recognizing this, Congress has often provided for compensation in past legislation that has retroactively invalidated patents. For example, the Atomic Energy Act of 1954 "revoked" existing patents on "any invention or discovery which is useful solely in the utilization of special nuclear material or atomic energy in an atomic weapon," while providing a process to provide just compensation to any such patent holder.

If Congress seeks to preclude the exercise of exclusive patent rights over COVID-19 medical countermeasures, it could pass legislation preventing the PTO from issuing such patents, or invalidating already-issued patents relating to countermeasures. In the latter case, some mechanism for compensation to the patent holder might be required under the Takings Clause. In either case, such legislation could raise issues under the United States' treaty obligations, including the treaty on Trade-Related Aspects of Intellectual Property Rights of the Marrakesh Agreement establishing the World Trade Organization (WTO), in which WTO members agree to make patents available in "all fields of technology," with some exceptions. In addition, preclusion of patent rights could reduce incentives to create and develop medical countermeasures against COVID-19.

Chapter 388

CORONAVIRUS DISEASE 2019 (COVID-19) POSES CHALLENGES FOR THE U.S. BLOOD SUPPLY*

Jared S. Sussman

The current Coronavirus Disease 2019 (COVID-19) outbreak may pose significant challenges for the United States' blood supply. Mitigation strategies to prevent the spread of COVID-19, such as closures of schools and workplaces, have led to blood drive cancellations, resulting in a critical blood supply shortage in the Pacific Northwest (specifically, western Washington and Oregon). School closures, event cancellations, and other mitigation strategies in other areas of the country may provide challenges for maintaining a sufficient blood supply. The management and distribution of the U.S. blood supply is largely coordinated by private organizations, with some oversight by the Department of Health and Human Services (HHS). Congress may consider how best to address critical storages, such as through HHS or the U.S. Food and Drug Administration's (FDA) authority over blood safety and donation guidance.

INDUSTRY AND BLOOD CENTER RESPONSE

The nation's blood supply is managed by a network of independent blood centers and the American Red Cross. On March 9, 2020, one blood center, Bloodworks Northwest, headquartered in Seattle, Washington, issued a press release warning that the Pacific Northwest blood supply is at the risk of collapse in coming days due to COVID-19 concerns. The release notes that the closure of schools, businesses, and events has led to the cancellation of blood drives in the area.

Immediate risk of blood supply collapse due to the COVID-19 outbreak is currently limited to the Pacific Northwest. However, blood drives may potentially be cancelled in other areas of the country as containment and mitigation strategies increase, which may lead to

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11238, dated March 13, 2020.

blood supply shortages in additional areas. Blood centers are also concerned that potential donors may choose not to donate over fears of contracting COVID-19 while at the blood center. Blood centers throughout the country and organizations representing the industry are urging individuals to donate blood to mitigate potential shortages. (For examples, see Kentucky Blood Center, New York Blood Center, and LifeServe Blood Center.)

Blood products have a limited shelf-life, and therefore ongoing donations are necessary. Blood can be mobilized and distributed regionally by blood center networks when a shortage exists at a blood center, but only to a certain extent given the limited shelf-life. HHS supports blood availability preparedness and response coordination through a number of roles and responsibilities.

BLOOD DONATION AND TRANSFUSION SAFETY

The industry is reinforcing the notion that blood donation is a safe activity. Bloodworks Northwest, for instance, relayed in its press release on the outbreak that it routinely sanitizes its facilities and equipment, and staff regularly implement infection control precautions. Furthermore, staff, donors, and volunteers are encouraged to stay home if they feel unwell. Other blood centers are including similar reassurances in their calls to donate.

On the day of donation, donors must have a normal temperature and present other signs of good health (21 C.F.R. § 630.10(f)). Blood centers are asking donors to follow-up after donating if diagnosed with COVID-19, as recommended by FDA.

FDA reports that there are no known cases of respiratory virus transmission by blood transfusion and there have been no reported cases of transfusion-transmitted COVID-19, but has issued recommendations to guide the blood donation activities of persons who may have been exposed.

FDA RECOMMENDATIONS ON BLOOD DONATION

On March 11, 2020, FDA published updated information for blood establishments regarding donation during the outbreak. The March 11 information suggests that some blood establishments may want to consider donor education, encourage self-deferral, and manage post-donation information about COVID-19. The March 11 information recommends that individuals self-defer from donating blood for 28 days after either (1) resolution of symptoms after a diagnosis of COVID-19 or (2) the last possible contact exposure to a person with a COVID-19 infection. Donors are also directed to report a subsequent diagnosis after donation.

Previous, now-outdated FDA information published on February 4, 2020, also recommended that individuals self-defer from donating blood for 28 days following travel to a location with a COVID-19 outbreak. However, some blood centers are still instructing potential donors to self-defer from donating if they recently traveled to areas with COVID-19 cases (for examples, see LifeServe Blood Center and Bloodworks Northwest). If these instructions remain in effect, they could potentially limit supply in areas that have the most critical need as many potential donors may meet the self-deferral criteria.

The March 11 information also recommends that blood centers “prepare and evaluate emergency plans to address challenges, such as effects on the availability of blood donors and staff.” FDA did not provide any specific guidance for the preparation of emergency plans for blood centers.

IMPLICATIONS FOR CONGRESS

Congress may direct FDA to issue more specific information to help blood centers educate potential donors as the outbreak evolves, to prevent travel deferrals, and to guide the development of emergency plans. Congress may also direct HHS to ensure that measures are in place to mobilize and distribute blood to blood centers, as needed. In addition, individual members of Congress may wish to communicate the safety of blood donation to constituents and to encourage donations at the local level.

Chapter 389

COVID-19: AN OVERVIEW OF TRADE-RELATED MEASURES TO ADDRESS ACCESS TO MEDICAL GOODS*

Nina M. Hart

ABSTRACT

As the coronavirus (COVID-19) pandemic continues, government officials around the world have raised questions and concerns about how to ensure that their countries have adequate access to, and supplies of, medical goods, including personal protective equipment (e.g., masks, gloves, garments), medical equipment (e.g., ventilators), and pharmaceuticals. This Sidebar presents an overview of some of the trade-related measures taken by the United States and its trading partners in their efforts to address these concerns, including: (1) introducing export restrictions; (2) reducing or eliminating tariffs; (3) revising import procedures; and (4) prioritizing domestic production. It then discusses possible legal challenges to each of these measures, as well as avenues for congressional action or oversight.

METHOD ONE: INTRODUCING EXPORT RESTRICTIONS

Several of the United States' trading partners have imposed export restrictions on certain medical goods to meet their domestic supply needs. For example, the European Union (EU) introduced export authorization measures that prohibit the export of personal protective equipment (e.g., masks, protective glasses, and garments) from the EU without prior regulatory approval. India restricted exports of twenty-six pharmaceutical components, as well as medicines and vitamins made from them, accounting for approximately ten percent of

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. LSB10424, dated March 20, 2020.

India's pharmaceutical exports. To date, the United States has not supported its trading partners' use of export restrictions to address potential supply shortages.

The World Trade Organization's (WTO's) international trade regime generally prohibits quantitative restrictions on the export of goods, whether in the form of export bans, licensing requirements, or other measures having similar restrictive effects. In light of this general rule, the export restrictions described above may arguably cause some to raise concerns. At the same time, however, three exceptions may apply. First, the general prohibition does not cover export restrictions "temporarily applied to prevent or relieve critical shortages of ... products essential to the exporting contracting party." Second, the WTO regime permits its Members to implement measures contrary to their general obligations if the measures are "necessary to protect human, animal or plant life or health" or "essential to the acquisition or distribution of products in general or local short supply." Any potentially WTO-inconsistent measures must also meet other conditions, including that their application not create "arbitrary or unjustifiable discrimination between countries where the same conditions prevail." Measures taken to address the acquisition or distribution of products in short supply must also be time-limited and conform to the principle that all WTO Members "are entitled to an equitable share of the international supply of such products." Third, the WTO does not prevent any Member from implementing measures "that it considers necessary for the protection of its essential security interests ... in time of war or other emergency in international relations."

It is uncertain whether the export restrictions imposed by WTO Members (or any future restrictions that may be imposed by other WTO Members, including the United States) to address concerns about shortages of medical supplies are WTO-inconsistent and, if so, fall within one of the exceptions, as this precise issue has not yet been litigated before the WTO's Dispute Settlement Body. However, in a joint study, the WTO and World Health Organization (WHO) indicated that some trade-restrictive measures used to address widespread infectious diseases are "unlikely to conflict with WTO rules," provided that they are time-limited and crafted to minimize trade disruptions. Nonetheless, the WHO has advised against export restrictions to address COVID-19, instead recommending that countries incentivize increased domestic production of the needed products (discussed below). The WTO Director-General has also stressed that "maintaining open trade and investment flows will be critical to protect jobs, prevent supply chain breakdown, and ensure that vital products do not become unaffordable for consumers."

METHOD TWO: REDUCING OR ELIMINATING TARIFFS

Since the onset of the COVID-19 pandemic, the cost of a number of medical goods has increased dramatically. For example, the cost of surgical masks has increased 600% and the cost of medical gowns has doubled.

To alleviate the financial pressure on firms and other entities that must buy these products, the United States has removed some tariffs on certain medical goods from China imposed under Section 301 of the Trade Act of 1974. However, some commentators remain concerned that the remaining Section 301 tariffs imposed by the Trump Administration may impair the United States' ability to respond to COVID-19. Some Members of Congress have urged the Administration to remove or suspend tariffs on a number of products from China to

alleviate the economic impact from COVID-19, including by reducing the cost for firms to purchase medical supplies.

Congress could potentially remove or eliminate tariffs, as it possesses constitutional authority to “lay and collect ... Duties” (i.e., tariffs). Alternatively, the President could “authorize the Secretary of the Treasury to permit ... the importation free of duty of food, clothing, and medical, surgical, and other supplies for use in emergency relief work” under Section 318 of the Tariff Act of 1930, after a declaration that “an emergency ... exist[s] by reason of a state of war, or otherwise.” The scope of Section 318 may raise the question of whether its broad delegation of authority may violate the non-delegation doctrine, which prohibits the transfer of legislative functions to the Executive without an “intelligible principle” to limit the Executive’s discretion when implementing such functions. However, a recent challenge to another trade statute that grants the President broad authority to restrict imports may suggest otherwise. Specifically, the U.S. Court of Appeals for the Federal Circuit upheld the constitutionality of Section 232 of the Trade Expansion Act of 1962, which permits the President to restrict imports if he determines they are entering the United States “in such quantities or under such circumstances as to threaten the national security.” As of the time of writing, no court has considered the legality of Section 318.

The impact of tariffs on access to medical goods has long been of interest to WTO Members, even in the absence of immediate public health crises. In 2006, they committed to negotiating the elimination of tariffs and non-tariff barriers on a number of healthcare-related goods. These negotiations remain ongoing.

METHOD THREE: REVISING IMPORT PROCEDURES

Most countries regulate the importation of medical goods for public health and safety reasons. For instance, in the United States, U.S. Customs and Border Protection (CBP) would need to approve the importation of medical devices and pharmaceutical products. CBP may assess, at the port of entry, whether the products to be imported satisfy customs rules, such as entry documentation, and comply with other U.S. laws and regulations, including the U.S. Food and Drug Administration’s governing statutes. Failure to satisfy these requirements can lead to delays in processing and release of products into the United States, or in some circumstances, to seizure of the goods.

To address procedural issues that could potentially delay access to medical goods, some countries have taken steps to streamline their customs procedures. China created a “green lane” system, which prioritizes the inspection and review of imported medical goods with the goal of reducing regulatory processing time before the goods may be released for use. Similarly, the EU recently introduced guidelines, instructing its Member States to create “green lanes” for freight transport to ensure access to “essential products,” including medicines and medical equipment.

Thus far, the United States has seemingly not publicly proposed amending its customs or other regulatory procedures in response to the COVID-19 pandemic. However, CBP has congressional authorization to “develop and implement screening and targeting capabilities, including ... prioritizing of passengers and cargo.” Thus, CBP may be able to create a “green lane” system, similar to those described above, to reduce processing times for medical goods.

Given that the creation of such a system may require CBP to complete a rulemaking process, it may not be feasible to implement this type of system to address COVID-19 (although CBP may be able to create a new regulation that would apply to any future emergencies). Congress could, however, consider using its constitutional authority to “regulate Commerce with foreign Nations” to more quickly implement new customs prioritization procedures.

METHOD FOUR: PRIORITIZING DOMESTIC PRODUCTION

As an alternative to reliance on cross-border supply chains, the United States and some of its trading partners have sought to prioritize domestic production of necessary goods, either by requiring manufacturers to complete orders of medical goods before orders of non-medical goods, or by imposing increased production requirements on these manufacturers. This reflects, at least in part, growing concern about supply chain security, as many countries import more health-related products than they export—as of 2010, only 24 countries out of 139 surveyed were net exporters of such products.

On March 18, 2020, President Trump issued an Executive Order authorizing the Secretary of Health and Human Services to use the Executive Branch’s authority under the Defense Production Act to address potential shortages in health and medical resources needed to respond to COVID-19. This Act permits the President, or agency to whom he delegates responsibility, to require that certain contracts or orders “take priority” over others, as well as to require companies to fulfill production orders “necessary or appropriate to promote the national defense.” The Act also allows the President to incentivize domestic production and ensure that essential products and their components “are available from reliable sources,” such as by restricting the suppliers, whether foreign or domestic, from whom manufacturers can obtain materials. While the Act does not envision a large role for Congress in its implementation (except with regard to wage and price controls), Congress may consider enhancing its oversight or authorization role. Additionally, to the extent that some Members of Congress may have questions as to the scope of “national defense,” Congress could consider amending the Act to clarify whether it applies to COVID-19 or any other future public health emergencies.

Other countries have also implemented or are considering similar measures. For example, Germany and Italy placed additional orders for ventilators and other health-related products, and Italy has directed its military to assist the country’s only domestic producer of ventilators to quadruple production. The United Kingdom is also assessing options for increasing domestic production of medical supplies. Such measures seemingly align with the WHO’s suggestion that “Governments should develop incentives for industry to ramp up production.” Such measures may be permitted under the WTO regime, provided they are not unlawful subsidies (e.g., subsidies that harm the industries of other WTO Members) under the WTO’s Agreement on Subsidies and Countervailing Measures, or, if the measures are potentially WTOinconsistent, provided that they fall within an exception (e.g., the public health or essential security exceptions described above).

Chapter 390

DEVELOPMENT AND REGULATION OF DOMESTIC DIAGNOSTIC TESTING FOR NOVEL CORONAVIRUS (COVID-19): FREQUENTLY ASKED QUESTIONS*

Amanda K. Sarata

ABSTRACT

On December 31, 2019, the World Health Organization (WHO) was informed of a cluster of pneumonia cases in Wuhan City, Hubei Province of China. Illnesses have since been linked to a disease caused by a previously unidentified strain of coronavirus, designated Coronavirus Disease 2019, or COVID-19. Despite containment efforts in China, the United States, and elsewhere, by late February there were indications that the COVID-19 outbreak may have entered a new phase, with community spread occurring or suspected in several countries other than China, including in the United States.

Diagnostic testing is a critical part of the public health response to and clinical management of COVID-19, caused by the SARS-CoV-2 virus. Efforts in the United States to develop and disseminate a test for COVID-19 have faced challenges. Manufacturing and quality issues with the nation's test—developed by the Centers for Disease Control and Prevention (CDC)—resulted in significant delay in access to testing throughout the country. In this context, on February 29, 2020, in an effort to facilitate the expansion of testing capacity as the first cases of community spread were confirmed in the United States, the Food and Drug Administration (FDA) announced a new policy, issued via agency guidance and effective immediately, that would allow certain laboratories—principally clinical and large commercial and reference laboratories—that have developed and validated their own COVID-19 diagnostic to begin to use the test prior to it receiving an Emergency Use Authorization (EUA) from the agency.

FDA's February 29 guidance aims to facilitate the expansion of diagnostic testing from the public health setting into the clinical health care and commercial settings. Doing so may help the country meet the increasing and substantial demand for testing generated by community spread of the disease and expanded clinical testing guidelines issued by

the CDC. This report does not address financing or coverage of diagnostic testing for COVID-19.

On December 31, 2019, the World Health Organization (WHO) was informed of a cluster of pneumonia cases in Wuhan City, Hubei Province of China. Illnesses have since been linked to a disease caused by a previously unidentified strain of coronavirus, designated Coronavirus Disease 2019, or COVID-19. Despite containment efforts in China, the United States, and elsewhere, by late February there were indications that the COVID-19 outbreak may have entered a new phase, with community spread occurring or suspected in several countries other than China, including in the United States.¹

Diagnostic testing is a critical part of the public health response to and clinical management of the COVID-19 caused by the SARS-CoV-2 virus. Efforts in the United States to develop and disseminate a test for COVID-19 have faced challenges. Manufacturing and quality issues with the nation's test—developed by the Centers for Disease Control and Prevention (CDC)—resulted in essentially all testing going through CDC's laboratory facility in Atlanta through early March, despite distribution of test kits to state and local public health labs beginning in early February.

CDC's initial test kits had to be remanufactured and redistributed, which, along with other factors, has significantly delayed access to testing throughout the country. It has been reported that the CDC's Atlanta laboratory is currently under investigation by the Department of Health and Human Services (HHS) for possible quality issues related to its manufacture of the test kits, which may have led to the contamination of one reagent and thus to the quality issues with the test.²

In this context, on February 29, 2020, in an effort to facilitate the expansion of testing capacity as the first cases of community spread were confirmed in the United States, the Food and Drug Administration (FDA) announced a significant new policy. This policy, issued via agency guidance and effective immediately, allows certain laboratories—principally clinical and commercial laboratories—that have developed and validated their own COVID-19 diagnostics to begin to use the tests prior to the test receiving an Emergency Use Authorization (EUA) from the agency.³

Diagnostic testing for COVID-19, in part because it is caused by a novel pathogen, has been led and carried out to date through the country's public health infrastructure. This includes primarily the CDC and the country's network of state and local public health laboratories. In contrast, in most situations, diagnostic testing is carried out by a number of facilities, including private commercial laboratories (e.g., Quest, LabCorp), hospital and other clinical laboratories, and laboratories in academic medical centers, among others.

FDA's February 29 guidance aims to facilitate the expansion of diagnostic testing from the public health setting into the clinical health care and commercial settings, leveraging

³ See generally FDA, "Policy for Diagnostics Testing in Laboratories Certified to Perform High Complexity Testing under CLIA prior to Emergency Use Authorization for Coronavirus Disease-2019 during the Public Health Emergency," February 29, 2020, <https://www.fda.gov/media/135659/download>.

significant standing resources throughout the country, including facilities, trained personnel, expertise, materials, and equipment. It is FDA's intention that this expansion will help the country meet the increasing and substantial demand for testing generated by community spread of the disease and expanded clinical testing guidelines issued by the CDC. In addition, because many cases of COVID-19 are reportedly mild or asymptomatic, widespread access to testing—which informs development of important metrics such as the case fatality rate—is critical to understanding the scope and extent of the disease in the United States, and to efficiently directing resources to mitigate its impact in the broader community.

Diagnostic tests—formally called *in vitro* diagnostic (IVD) devices—may be commercially developed and distributed as “kits” or developed, validated, and carried out by a single laboratory. This second type of test—known as a laboratory-developed test, or an LDT—is the more commonly used type of test because of its flexibility and differing federal regulatory requirements, among other reasons. Although the CDC's test is being manufactured as a test kit and initially has been distributed to specific CDC-qualified labs, the FDA guidance targets LDTs that are generally carried out in clinical and academic settings or private commercial laboratories. All clinical laboratories in the United States, regardless of whether they are part of the country's public health infrastructure or part of the health care delivery system, are regulated by the Clinical Laboratory Improvement Amendments of 1988 (CLIA) program, administered by the Centers for Medicare & Medicaid Services (CMS).

Federal agencies involved in the regulation of IVDs include FDA and CMS. FDA derives its authority to regulate the sale and distribution of medical devices, such as IVDs, from the Federal Food, Drug, and Cosmetics Act (FFDCA) and the Public Health Service Act (PHSA). CMS's authority to regulate IVDs is through CLIA (P.L. 100-578). FDA regulates the safety and effectiveness of diagnostic tests, as well as the quality of the design and manufacture of the diagnostic test. CMS regulates the quality of clinical laboratories and the clinical testing process.

DIAGNOSTIC TESTS

What Are IVD Tests?

In vitro diagnostic devices are defined in FDA regulation as a specific subset of medical devices that include “reagents, instruments, and systems intended for use in the diagnosis of disease or other conditions ... in order to cure, mitigate, treat, or prevent disease ... [s]uch products are intended for use in the collection, preparation, and examination of specimens taken from the human body.” As indicated by this definition, an IVD may also include components of tests, which can include both non-diagnostic ingredients, called general purpose reagents (GPRs), and the active ingredient in a diagnostic test, referred to as the analyte specific reagent (ASR).

In general, an IVD device may be a “commercial test kit” (a product developed, produced, and sold by a manufacturer for distribution to multiple laboratories) or a “laboratory developed test” (a product developed by and used in a single laboratory). LDTs may use components (e.g., general purpose reagents like a buffer) that are either manufactured in-house by the laboratory or commercially developed and distributed.

What Is an LDT?

A laboratory-developed test is a class of IVD that is designed, manufactured, and used within a single laboratory. LDTs are often used to test for conditions or diseases that are either rapidly changing (e.g., new strains of known infectious diseases) or the subject of quickly advancing scientific research (e.g., genomic testing for cancer). The majority of genetic tests—a type of IVD that analyzes various aspects of an individual's genetic material (e.g., DNA, RNA)—are LDTs.

How Are IVD Tests Regulated?

In general, oversight of in vitro diagnostic devices focuses on ensuring their safety and effectiveness; their accuracy and reliability; the quality of clinical laboratories that carry out IVD testing; the utility of the information generated by IVDs in clinician and patient decision-making; and the truthfulness of claims made about IVDs that are marketed directly to consumers. As with other medical devices, the application of FDA regulatory requirements to IVDs depends on the IVD's risk classification according to its intended use. Classification is based, in turn, on the risk the device poses to the patient. For IVDs, which are informational tests, the risk to the patient is that of an incorrect test result, either a false positive or a false negative result, either of which may cause serious harm to the individual. In the case of infectious diseases—for example, COVID-19—the risk of a false negative test extends beyond the individual patient into the community at large. The FDA has three classes of medical device: Class I (low risk), Class II (moderate risk), and Class III (high risk). Regulatory controls are dependent on the class of a given medical device. COVID-19 diagnostics would most likely fall in Class III, as they would be considered to be high-risk devices.

How Are LDTs Regulated?

The regulation of laboratory-developed tests has been the subject of ongoing debate over the past 20 years, driven in large part by an increase in the number and complexity of genetic tests over this time. In general, the FDA has maintained that it has clear regulatory authority over LDTs, as it does with all IVDs that meet the definition of medical device in the FFDCA.⁴ However, the FDA traditionally exercised enforcement discretion over LDTs—choosing not to enforce applicable statutory and regulatory requirements with respect to such tests—meaning that most of these tests have neither undergone premarket review nor received FDA clearance or approval for marketing. To date, FDA has instead focused its enforcement efforts on commercial IVD kits, which are broadly commercially marketed. In recent years, despite the absence of specific agency guidance on the regulation of LDTs, FDA has nevertheless begun to assert authority over LDTs, and specifically over some direct-to-consumer (DTC) genetic tests, that it considers to be higher-risk tests.

⁴ The term *medical device* is defined in FFDCA §201(h) [21 U.S.C. §321(h)].

What Is CLIA and How Is It Involved in LDT Regulation?

CLIA of 1988 provides CMS with authority to regulate clinical laboratories.⁵ CLIA establishes quality standards for clinical laboratory testing and a certification program for clinical laboratories that perform testing using IVD devices. All laboratories that perform diagnostic testing for health-related reasons (i.e., with results returned to the patient or a health care practitioner) are regulated by CMS under the authority of CLIA. For CLIA to apply, testing must be carried out on a human specimen. CLIA certification is based on the level of complexity of testing that the laboratory performs, specifically (1) low (therefore, waived) complexity, (2) moderate complexity, and (3) high complexity. FDA is responsible for categorizing tests according to their level of complexity. CLIA requirements are used to evaluate a test's *analytical validity*, defined as the ability of a test to detect or measure the analyte it is intended to detect or measure. Laboratories that perform moderate- and high-complexity testing must meet specific standards and requirements as a condition of certification, including proficiency testing (PT), patient test management, quality control, personnel qualifications, and quality assurance. All LDTs, including genetic tests offered as LDTs, are considered high-complexity tests under CLIA. All COVID-19 diagnostics would be considered to be high complexity tests under CLIA.

How Are IVDs Regulated by the FDA during an Emergency Such as the Outbreak of COVID-19?

In certain public health or other emergency situations, the HHS Secretary may declare that existing circumstances justify the use of unapproved medical products for certain uses, or approved medical products for unapproved uses.⁶ This declaration facilitates access to not-yet- approved medical products in an expedited manner during certain emergency situations. In the case of the COVID-19 disease, HHS Secretary Azar determined that “there is a public health emergency and [declared] that circumstances exist justifying the authorization of emergency use of in vitro diagnostics for detection and/or diagnosis of the novel coronavirus.”⁷ On the basis of this declaration, FDA issued an Emergency Use Authorization authorizing the emergency use of the CDC-developed diagnostic test for COVID-19.⁸ The FDA also issued an EUA to the state of New York for an LDT developed by the state public health labs. To date, these are the only two EUAs for coronavirus diagnostics that the FDA has issued.⁹

⁸ Letter of authorization from FDA to CDC, advising of the authorization for emergency use of the CDC-developed diagnostic test, available at “Novel coronavirus (COVID-2019) EUA Information” on the FDA web page “Emergency Use Authorization,” <https://www.fda.gov/emergency-preparedness-and-response/mcm-legal-regulatory-and-policy-framework/emergency-use-authorization>.

⁹ FDA, Emergency Use Authorization, <https://www.fda.gov/emergency-preparedness-and-response/mcm-legal-regulatory-and-policy-framework/emergency-use-authorization>.

How Does the Emergency Use Authority Apply to LDTs if They Are Generally Exempted from Premarket Requirements?

During an emergency, all laboratory-developed tests testing for the relevant pathogen (in this case, SARS-CoV-2) must either be approved, cleared, or authorized under an EUA to be legally carried out. As noted above, FDA generally waives most regulatory requirements (e.g., premarket review) for LDTs in normal situations; nevertheless, LDTs may only be used with authorization (e.g., an EUA) during an emergency declaration pursuant to FFDCa Section 564.¹⁰ That is, statutory requirements under FFDCa Section 564 apply to LDTs as they do to other medical products, and they apply to both commercial test kits—which are normally subject to FDA regulatory requirements—and to LDTs.

The EUA process is usually used to expedite access to medical products that would otherwise need premarket approval or clearance in emergency situations. However, because premarket approval requirements for LDTs are generally waived through enforcement discretion by the agency, the EUA represents additional regulatory requirements for the use of an LDT in emergency situations. This is because, among other things, in the case of a communicable disease, the test result has implications beyond the individual being tested, and so a false negative result could have serious consequences for the community.¹¹ Therefore, FDA states that these tests need an EUA in an emergency prior to clinical use as do other medical products. In contrast, for commercial test kits, the EUA represents an abbreviated mechanism that allows the unapproved product to be used without undergoing the FDA premarket review typically required (for a complex molecular test for a novel pathogen, that review would generally be a Premarket Approval, or PMA, for high-risk medical devices).

Despite a request from the Association of Public Health Laboratories (APHL) to FDA, the agency declined to exercise enforcement discretion with respect to LDTs that detect SARS-CoV-2 and diagnose COVID-19 and the requirement that they receive an EUA prior to use. APHL maintains that these labs are regulated by CLIA, and that this regulatory oversight is sufficient.¹² However, on February 29, 2020, FDA announced a new policy allowing certain laboratories that have developed and validated COVID-19 LDTs to begin to use the test clinically *prior* to it receiving an EUA from the agency but *after* validation of the test and notification of the agency (see “What Steps Did FDA Take to Expand Testing Capacity in Response to the Problems with CDC’s Test?”).¹³

THE CDC 2019-NOVEL CORONAVIRUS (2019-nCoV) REAL-TIME REVERSE TRANSCRIPTASE (RT)-PCR DIAGNOSTIC PANEL

How Does the CDC's COVID-19 Diagnostic Test Work?

The diagnostic test developed by the CDC, called the 2019-Novel Coronavirus (2019-nCoV) Real-Time Reverse Transcriptase (RT)-PCR Diagnostic Panel, is a complex molecular diagnostic test that relies on generally standard molecular biology laboratory techniques. Specifically, the test uses a technique called Polymerase Chain Reaction (PCR), a standard *in vitro* technique for amplification of DNA. Because the SARS-CoV-2 virus—the virus that causes COVID-19—is an RNA¹⁴ virus, the RNA must be first reverse transcribed to generate copy DNA, or cDNA, which is then amplified (multiple copies are generated) using PCR. PCR relies on primers—very short single stranded pieces of DNA that are complementary to and bind with specific regions of the viral genome and thus define the specific genomic region to be amplified. The test then relies on a probe, or a single-stranded piece of DNA that is chemically or radioactively labelled, that can bind to and thus detect the amplified target portion of the viral genetic material.

Figure 1. Polymerase chain reaction overview.

CDC's original test used three sets of primers and probes: two to target specific regions of a designated gene within the SARS-CoV-2 viral genome, and a third that was specific to all SARS-like coronaviruses (see "What Quality Problems Did the CDC's Test Experience on Rollout to the State and Local Public Health Laboratories?"). The test also includes a number of authorized control samples, including a positive control for SARS-CoV-2 and a "no template control" to test for system contamination. Together, these controls help ensure that the test is functioning properly.

¹⁴ RNA stands for ribonucleic acid. RNA is genetic material with a slightly different chemical composition from DNA, or deoxyribonucleic acid.

What Type of IVD Is the CDC's Test and Who May Carry It Out?

The CDC's test is being developed by the agency as a test kit and is generally authorized to be distributed to state and local public health laboratories to augment public health testing capacity. The test received an EUA from the FDA on February 4, 2020, under which "authorized laboratories" may receive and carry out the test despite the fact that it is not FDA-approved or FDA-cleared, and that it does not meet all related regulatory requirements for marketing.¹⁵ The EUA notes that "[t]esting is limited to qualified laboratories designated by CDC and, in the United States, certified under the Clinical Laboratory Improvement Amendments of 1988 (CLIA), (42 U.S.C. §263a), to perform high complexity tests."¹⁶ CDC-qualified laboratories with a CLIA certification for high-complexity testing able to receive the test kits include U.S. state and local public health laboratories, Department of Defense (DOD) laboratories, and select international laboratories. The public health laboratories must verify the test themselves prior to using it, and are currently required to send presumptive positive cases back to the CDC in Atlanta for confirmatory testing by the agency.

What Is the Role of the Commercial Manufacturer IDT in the Development and Distribution of the CDC's Test Kit?

The Trump Administration had estimated that approximately 1 million tests would be broadly available imminently, facilitated by leveraging manufacturing of the CDC test kit by a private company, Integrated DNA Technologies (IDT), a manufacturer that has been working with CDC.¹⁷ According to HHS Secretary Azar on March 5, 2020, IDT will send the CDC test kit to "hospitals, other labs around the country, commercial, public health ... labs" by the end of the week of March 2.¹⁸ The test kit being manufactured by IDT, identical to the CDC test kit and referred to as "IDT 2019-novel coronavirus kit," is being qualified by CDC in lots, and FDA reports that these CDC-qualified, IDT-manufactured test kits are covered by the CDC's EUA authorization of February 4, 2020.¹⁹

FDA notes that if a lab purchases a test kit from IDT, the laboratory does not need its own EUA to carry it out, but that "[t]esting using CDC's EUA-authorized protocol and CDC qualified lots of reagents is considered to be testing done under the CDC's EUA. Labs performing such testing should follow any applicable conditions set forth in the EUA."²⁰ LabCorp, a large commercial laboratory, is already reporting that it can perform the CDC test "if needed to meet testing demand" and that the test is only for use with "authorized

specimens collected from individuals who meet CDC criteria for COVID-19 testing.”²¹ IDT is manufacturing test kits in two sizes, with the largest having a capacity of 500 reactions (approximately 250 individual patients).²²

What Quality Problems Did the CDC’s Test Experience on Rollout to the State and Local Public Health Laboratories?

As noted above, the CDC’s test kit used three sets of probes and primers—or reagents—to detect and identify viral DNA beyond that specific to COVID-19. One of these reagents, the one meant to detect any SARS-like coronavirus including SARS-CoV-2, was returning inconclusive results. In response, the CDC validated a new protocol for their test that allows it to be run excluding the faulty reagent, running the test with only the other two diagnostic components. CDC has the authority to modify the test through enforcement discretion granted by FDA.²³ The agency determined that the exclusion of this reagent does not affect the accuracy or the sensitivity and specificity of the test.

Certain laboratories have continued to experience problems running the test, even when using the modified protocol, with at least one laboratory reporting that the first reagent was also returning inconclusive results. This problem severely limited the state and local public health laboratories’ ability to carry out the CDC’s test.

In response to these issues, the New York State Department of Health requested and was granted the FDA’s second EUA for its own laboratory-developed test, the New York SARS-CoV-2 Real-time RT-PCR Diagnostic Panel.²⁴ Testing is limited under the EUA to two laboratories in New York—the Wadsworth Center, New York State Department of Public Health, and the New York City Department of Health and Mental Hygiene, Public Health Laboratories. New York was one of the states that had continued difficulty implementing CDC’s original test kit, even with the modified protocol.

In response, CDC is also manufacturing new test kits after reportedly resolving the manufacturing issue that affected the original test kit. This time, however, CDC is manufacturing test kits with only the two reagents that were unaffected by the quality issue—that are specific to SARS-CoV-2—and those kits are being made available to qualified CDC labs through the International Reagent Resource.^{25,26} These test kits are expected to result in the public health laboratories having capacity to test up to 75,000 patients.²⁷

²⁷ CDC, “Coronavirus Disease 2019 (COVID-19) Situation Summary,” Updated March 3, 2020, <https://www.cdc.gov/coronavirus/2019-ncov/summary.html>.

Some believe that the CDC's choice to develop and mitigate quality problems with its own COVID-19 diagnostic when an accepted diagnostic was available through the World Health Organization (WHO), which was efficiently distributing a German-developed test globally early in the outbreak, was a decision that cost the United States time in its response to the virus's introduction and spread in the country.²⁸ Some speculated about the use of the third reagent—that was to detect SARS-like coronaviruses—and whether it had been strictly necessary if the test was still accurate at diagnosing COVID-19 without that reagent included in the test at all, or if it had instead overcomplicated the test.²⁹ In general, there have been questions raised about the CDC's handling of the development and distribution of its test, and its response to the quality problems that occurred, and the impact this may have had on the country's ability to detect community spread of the disease before it occurred more widely.³⁰

What Steps Did FDA Take to Expand Testing Capacity in Response to the Problems with CDC's Test?

On February 29, 2020, as problems with the rollout of the CDC-developed diagnostic test continued, FDA announced a new policy to immediately leverage LDTs developed in high-complexity commercial, reference, and clinical laboratories nationwide to expand testing capacity. Specifically, the new agency guidance allows CLIA-certified high-complexity laboratories that have developed and validated their own COVID-19 diagnostics to use the tests while the laboratory is preparing, and FDA is reviewing, their EUA submission.^{31,32}

The FDA guidance states that laboratories have 15 days after validating their test to submit an EUA application to FDA, and the guidance recommends confirming the test's first five negative and positive results against an EUA-authorized diagnostic. According to FDA, it “does not intend to object to the use of these tests for clinical testing while the laboratories are pursuing an EUA with the FDA. Importantly, this policy only applies to laboratories that are certified to perform high-complexity testing consistent with requirements under Clinical Laboratory Improvement Amendments.”³³ The guidance includes detailed information about FDA's expected methods for test validation.

Pursuant to this FDA guidance, on March 5, 2020, LabCorp announced that it had begun offering its LDT, the LabCorp 2019 Novel Coronavirus (COVID-19), NAA test “for ordering

Chapter 391

THE STAFFORD ACT EMERGENCY DECLARATION FOR COVID-19*

Erica A. Lee, Elizabeth M. Webster and Bruce R. Lindsay

This Insight provides an overview of emergency declarations under the Robert T. Stafford Disaster Relief and Emergency Assistance Act (hereinafter the Stafford Act, P.L. 93-288, as amended; 42 U.S.C. §§5121 et seq.). It describes the forms of assistance authorized pursuant to President Donald J. Trump's March 13, 2020 emergency declaration under the Stafford Act in all U.S. states and territories in response to the coronavirus disease 2019 (COVID-19) pandemic.

STAFFORD ACT EMERGENCY DECLARATION FOR COVID-19

The President's emergency declaration, pursuant to Stafford Act Section 501(b), authorized assistance for COVID-19 response efforts for all U.S. states, territories, and the District of Columbia. There was no precedent for a nationwide Stafford Act declaration. Generally, the governor of an affected state/territory or tribal chief executive of an affected Indian tribal government requests the President approve a Stafford Act declaration for specific jurisdictions and types of needed assistance, and the President makes the determination in consultation with FEMA. It is rare for the President to declare an emergency without a governor or chief executive's request; examples include the explosion at the federal courthouse in Oklahoma City and the loss of the Space Shuttle Columbia. Like the COVID-19 emergency declaration, these declarations were authorized under Stafford Act Section 501(b), for certain emergencies involving federal primary responsibility (42 U.S.C. §5191).

The Department of Health and Human Services (HHS) remains the lead agency for the federal response to COVID-19 (see also 42 U.S.C. 300hh(a)). Assistance authorized through the Stafford Act is to supplement and support the efforts of HHS and state, territorial, tribal,

* This is an edited, reformatted and augmented version of a Congressional Research Service publication IN11251, prepared for Members and Committees of Congress dated March 13, 2020.

and local governments. The Stafford Act does not supplant or supersede other federal authorities, including public health authorities exercised by the Secretary of HHS.

COMPARING STAFFORD ACT DECLARATIONS

The Stafford Act authorizes the President to issue either “emergency” or “major disaster” declarations. An emergency is broadly defined, and may include public health incidents. Although infectious disease events are not listed in the definition of a major disaster, President Trump stated that he “believe[s] that the disaster is of such severity and magnitude nationwide that requests for a declaration of a major disaster ... may be appropriate.”

Table 1 lists the forms of assistance available pursuant to each type of declaration.

Table 1. Assistance available under Stafford Act Declarations

	Emergency Declaration	Major Disaster Declaration
Public Assistance (PA)	Emergency Work Category A – Debris Removal Category B – Emergency Protective Measures	Emergency Work Category A – Debris Removal Category B – Emergency Protective Measures Permanent Work Categories C-G – Restoration of damaged facilities
Individual Assistance (IA)	Individuals and Households Program (IHP)	IHP Crisis Counseling Program Disaster Case Management Disaster Unemployment Assistance Disaster Legal Services Disaster Supplemental Nutrition Assistance Program
Hazard Mitigation Assistance (HMA)	Not Available	Hazard Mitigation Grant Program

Source: FEMA, “The Disaster Declaration Process.”

PUBLIC ASSISTANCE

Emergency declarations typically authorize certain types of Public Assistance (PA), which provides financial assistance to supplement a state, territorial, or tribal government’s ability to respond to an incident. Emergency declarations may authorize PA “emergency work” undertaken to save lives, protect property and public health and safety, and lessen or avert the threat of a catastrophe. The two forms of PA “emergency work” are debris removal (authorized under Stafford Act Sections 403, 407, and 502) and emergency protective measures (authorized under Stafford Act Sections 403, 418, 419, and 502).

When PA is authorized, a state, territory, or tribe becomes the PA grant recipient. Local governments and certain nonprofit entities may apply for grant funds through the recipient. The Stafford Act authorizes FEMA to reimburse not less than 75% of the eligible costs of specific types of work undertaken by eligible PA applicants.

Aside from eligibility restrictions, the amount of money that can be awarded for any single applicant or declaration through the PA program is not limited. However, the President must notify Congress when assistance provided for an emergency declaration exceeds \$5 million (42 U.S.C. §5193).

PUBLIC ASSISTANCE FOR COVID-19 EMERGENCY DECLARATION

The Stafford Act emergency declaration for COVID-19 authorized only one form of assistance: PA emergency protective measures. Applicants are to be reimbursed for 75% of eligible costs incurred while performing emergency protective measures. FEMA will not reimburse work supported by the authorities of another federal agency (42 U.S.C. §5155).

Emergency protective measures encompass a wide range of activities. According to a FEMA news release on the COVID-19 emergency declaration, reimbursable activities may include “activation of State Emergency Operations Centers, National Guard costs, law enforcement and other measures necessary to protect public health and safety.” Additionally, FEMA may reimburse costs for overtime labor performed by applicants’ budgeted employees and for overtime and regular-time labor performed by unbudgeted employees engaged in eligible work, per 44 C.F.R. §206.228. General FEMA guidance includes the following activities that may be relevant to a pandemic in a non-exclusive list of eligible emergency protective measures. FEMA has not yet specifically authorized these activities for COVID-19 response. Disaster-specific guidance may provide more information.

- Transporting and pre-positioning equipment and resources for response;
- Emergency Operation Center (EOC)-related costs;
- Supplies and commodities;
- Limited, uninsured emergency medical care and transport up to 30 days from the declaration date, unless extended by FEMA. Eligible care includes uninsured vaccinations, durable and consumable medical equipment and supplies, temporary medical facilities, and medical waste disposal;
- Evacuation and sheltering. Generally, FEMA only provides assistance for congregate sheltering, though non-congregate sheltering may be authorized upon request;
- Limited child care;
- Security, including law enforcement;
- Use or lease of temporary generators for facilities that provide essential services;
- Public dissemination of hazard information; and
- Mass mortuary services.

INDIVIDUAL ASSISTANCE

The FEMA Individuals and Households Program (IHP) may be available following a Stafford Act emergency declaration. IA was not authorized pursuant to the initial emergency declaration for COVID-19. An amended emergency declaration or a major disaster declaration could authorize different forms of IA.

Chapter 392

DIVISION B OF THE CORONAVIRUS AID, RELIEF, AND ECONOMIC SECURITY (CARES) ACT—RELIEF FOR INDIVIDUALS, FAMILIES, AND BUSINESSES*

*Molly F. Sherlock, Jane G. Gravelle, Margot L. Crandall-Hollick,
Donald J. Marples and Grant A. Driessen*

Congress is considering a number of proposals that seek to mitigate the economic effects of the COVID-19 pandemic. One such proposal, the Coronavirus Aid, Relief, and Economic Security (CARES) Act (S. 3548), was introduced in the Senate on March 19, 2020. Division B of S. 3548 includes tax relief for individuals and businesses, including

- a one-time rebate to taxpayers;
- a delay of the individual tax filing deadline for tax year 2019;
- modification of the tax treatment of certain retirement fund withdrawals and charitable contributions;
- a delay of employer payroll taxes and taxes paid by certain corporations; and
- a variety of changes to the tax treatment of business income and net operating losses.

This is the latest in a series of legislative packages addressing the COVID-19 pandemic. Two bills have already been enacted into law: the Coronavirus Preparedness and Response Supplemental Appropriations Act, 2020 (P.L. 116-123) and the Families First Coronavirus Response Act (P.L. 116-127).

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. R46279, dated March 20, 2020.

This report briefly summarizes the major provisions in Division B of S. 3548 (Table 1).¹ Links to CRS resources that offer additional information are provided. Provision summaries reflect the language in S. 3548 as introduced; legislative discussions concerning S. 3548 and other stimulus proposals are ongoing.

Table 1. Provisions in Division B of the CARES Act (S. 3548)

Provision	Description	CRS Resources
<i>Title I—Rebates and Other Individual Provisions</i>		
2020 recovery rebates for individuals	Credit against 2020 income taxes, but advanced, generally based on 2018 income tax returns. Credit equals the greater of (1) taxpayer's <i>net income tax liability</i> up to \$1,200 (\$2,400 for married joint filers). Net income tax liability is income tax liability <i>before</i> the child tax credit and refundable tax credits (like the EITC); or (2) \$600 (\$1,200 for married joint filers) if the taxpayer has <i>qualifying income</i> . To have qualifying income, taxpayer must have either (a) at least \$2,500 in total of earned income, social security income, or veterans' benefits, or (b) gross income above the taxpayer's standard deduction and \$1 of net income tax liability. Taxpayers eligible for the credit can also receive \$500 for each child eligible for the child credit. The total credit phases out at a rate of 5% of adjusted gross income (AGI) above \$75,000 (\$150,000 for married joint returns). All individuals must have social security numbers. Taxpayers must have filed a 2018 return (or file a 2019 return if they did not file a 2018 return) in order to get a rebate in 2020. Otherwise, it can be claimed on a 2020 income tax return.	For more, see • CRS Insight IN11255, <i>COVID-19 and Stimulus Payments to Individuals: How Did the 2008 Recovery Rebates Work?</i>, by Margot L. Crandall-Hollick. • CRS Insight IN11247, <i>COVID-19 and Stimulus Payments to Individuals: Considerations on Using Advanced Refundable Credits as Economic Stimulus</i>, by Margot L. Crandall-Hollick. • CRS Insight IN11256, <i>COVID-19 and Direct Payments to Individuals: Historical Precedents</i>, by Gene Falk. • CRS Insight IN11234, <i>Tax Cuts as Fiscal Stimulus: Comparing a Payroll Tax Cut to a One-Time Tax Rebate</i>, by Molly F. Sherlock and Donald J. Marples. • CRS Report RS21126, <i>Tax Cuts and Economic Stimulus: How Effective Are the Alternatives?</i>, by Jane G. Gravelle.
Delay of certain deadlines	Tax filing deadline extended from April 15, 2020, to July 15, 2020, to align with the extended payment deadline. a Allows individuals required to make estimated tax payments to postpone such payments until October 15, 2020.	For more on IRS administrative relief for tax filing deadlines following disasters, see • CRS Report R45864, <i>Tax Policy and Disaster Recovery</i>, by Molly F. Sherlock and Jennifer Teefy.
Special rules for use of retirement funds	For retirement plan distributions, the provision provides an exception to the 10% early withdrawal penalty for distributions up to \$100,000 for coronavirus-related purposes. Income from such distributions would be recognized over three years, and taxpayers can recontribute funds to an eligible retirement plan within three years without regard to the year's contribution cap. Loan limits from retirement plans are increased from \$50,000 to \$100,000 and repayment deadline is delayed.	For more on disaster-related special retirement fund access, see • CRS Report R45864, <i>Tax Policy and Disaster Recovery</i>, by Molly F. Sherlock and Jennifer Teefy. • CRS In Focus IF11447, <i>COVID-19: Social Insurance and Other Income-Support Options for Those Unable to Work</i>, coordinated by Laura Haltzel.

¹ Other tax-related provisions included in other divisions of the CARES Act, and not discussed in this report, include changes that would temporarily suspend excise taxes related to aviation; provide a temporary tax exemption for certain telehealth services; temporarily include certain over-the-counter medical costs as qualified medical expenses for tax purposes; extend the sequestration on direct spending by one year, to 2030; and temporarily provide advance refunding of payroll tax credits for sick leave and paid family leave. For more on the sick and family leave payroll tax credits, see CRS Insight IN11243, *Tax Credit for Paid Sick and Family Leave in the Families First Coronavirus Response Act (H.R. 6201) (Updated)*, by Molly F. Sherlock.

Provision	Description	CRS Resources
<i>Title I—Rebates and Other Individual Provisions</i>		
Allowance of partial above-the-line deduction for charitable contributions	An above-the-line deduction for cash contributions of up to \$300 is made available for taxpayers not itemizing deductions. This deduction would be allowed to taxpayers who do not itemize deductions.	For more on the tax treatment of charitable contributions, see - CRS Report R45922, <i>Tax Issues Relating to Charitable Contributions and Organizations</i>, by Jane G. Gravelle, Donald J. Marples, and Molly F. Sherlock. - CRS In Focus IF11022, <i>The Charitable Deduction for Individuals</i>, by Margot L. Crandall-Hollick and Molly F. Sherlock.
Modification of limitations on charitable contributions during 2020	Income limits apply to both individual and charitable contribution deductions. This provision would suspend the 50% of AGI limit on cash contributions for individuals for 2020. The corporate deduction limit would be increased from 10% of taxable income to 25% for cash contributions. The limit on the deduction of food inventory would be increased from 15% to 25%. The increased limits do not apply to contributions to private foundations and donor-advised funds.	For more on disaster-related changes in charitable giving limits, see - CRS Report R45864, <i>Tax Policy and Disaster Recovery</i>, by Molly F. Sherlock and Jennifer Teefy. For more on the tax treatment of charitable contributions, see - CRS Report R45922, <i>Tax Issues Relating to Charitable Contributions and Organizations</i>, by Jane G. Gravelle, Donald J. Marples, and Molly F. Sherlock. - CRS In Focus IF11022, <i>The Charitable Deduction for Individuals</i>, by Margot L. Crandall-Hollick and Molly F. Sherlock.
<i>Title II—Business Provisions</i>		
Delay of estimated tax payments for corporations	Corporations would be allowed to postpone estimated tax payments to October 15, 2020.	
Delay of payment of employer payroll taxes	Employers and self-employed individuals would be able to defer, or postpone, the employer share of the Social Security payroll tax. Deferred tax liability would be paid in two installments: one due by December 31, 2021, and the second by December 31, 2022. The Social Security trust funds would not be affected.	For more, see CRS Insight IN11260, <i>COVID-19 Economic Stimulus: Business Payroll Tax Cuts</i>, by Molly F. Sherlock and Donald J. Marples.
Modifications for net operating losses	The provision would allow carrybacks for up to five years for net operating losses (NOLs) recorded in tax years 2018, 2019, and 2020. NOL carryback capabilities were repealed by the 2017 tax revision (P.L. 115-97), and were previously allowed for up to two years. This provision would also temporarily lift the income limitation applicable to the corporate income tax treatment of NOLs under current law.	For more, see CRS Insight IN11240, <i>COVID-19: Potential Role of Net Operating Loss (NOL) Carrybacks in Addressing the Economic Effects</i>, by Mark P. Keightley.
Modification of limitation on losses for taxpayers other than corporations	This provision allows taxpayers not subject to the corporate income tax that incur NOLs, including pass-through businesses and sole proprietorships, to receive the temporary NOL carryback capabilities provided to corporations, as described above.	For more, see CRS Insight IN11240, <i>COVID-19: Potential Role of Net Operating Loss (NOL) Carrybacks in Addressing the Economic Effects</i>, by Mark P. Keightley.
Modification of credit for prior year minimum tax liability of corporations	The corporate alternative minimum tax (AMT) was repealed by the 2017 tax revision (P.L. 115-97). Corporations having AMT credits (for prior year AMT payments) were allowed to claim the credits against regular tax liability for tax years through 2021. This provision makes these credits refundable.	For more on the corporate AMT before its repeal, see CRS In Focus IF10705, <i>Tax Reform: The Alternative Minimum Tax</i>, by Donald J. Marples.

Table 1. (Continued)

Provision	Description	CRS Resources
<i>Title II—Business Provisions</i>		
Modification of limitation on business interest	The 2017 tax revision (P.L. 115-97) reduced the limit on the deduction for net interest from 50% to 30% of adjusted taxable income (income before taxes, interest deductions, and depreciation, amortization or depletion deductions). P.L. 115-97 also eliminated the rule that restricted net interest deduction limits to firms with a debt-to-equity ratio above 1.5. These revisions were adopted, in part, to reduce profit-shifting by multinational corporations (by borrowing in the United States). This provision increases the limit to 50% for 2019 and 2020.	For more, see CRS Report R45186, Issues in International Corporate Taxation: The 2017 Revision (P.L. 115-97), by Jane G. Gravelle and Donald J. Marples.
Technical amendments regarding qualified improvement property	The 2017 tax revision (P.L. 115-97) increased the period for deducting the cost of qualified improvement property (leasehold, restaurant, and retail property improvements) from 15 years to 39 years. This change was apparently a technical error that also prevented these investments from being expensed immediately (sometimes referred to as bonus depreciation). This provision allows these investments to be expensed.	For more, see CRS In Focus IF11187, Qualified Improvement Property and the 2017 Tax Revision (P.L. 115-97), by Gary Guenther.
Installments not to prevent credit or refund of overpayments or increase estimated taxes	As part of the transition to a new international tax regime under the 2017 tax revision (P.L. 115-97), firms were required to pay taxes on their prior untaxed foreign earnings (the repatriation tax). Firms could elect to pay these taxes in eight annual installments. Due to what was apparently a technical error, firms that overpaid their regular taxes in 2017 could not receive a refund if they owed taxes on repatriations. This provision allows firms to receive refunds for 2017.	For more, see CRS Report R45186, Issues in International Corporate Taxation: The 2017 Revision (P.L. 115-97), by Jane G. Gravelle and Donald J. Marples.
Restoration of limitation on downward attribution of stock ownership in applying constructive ownership rules	The 2017 tax revision (P.L. 115-97) treats stock owned by a foreign person as attributable to a U.S. entity owned by the foreign person (“downward attribution”). As a result, stock owned by a foreign person may generally be attributed to (1) a U.S. corporation, 10% of the value of the stock of which is owned, directly or indirectly, by the foreign person; (2) a U.S. partnership in which the foreign person is a partner; and (3) certain U.S. trusts if the foreign person is a beneficiary or, in certain circumstances, a grantor or a substantial owner. Downward attribution rules can result in additional tax to the U.S. entity under rules taxing certain income of controlled foreign corporations. This provision limits the application of the downward application rules to a U.S. corporation owning, directly or indirectly, 50% of the value of stock.	For more, see CRS Report R45186, Issues in International Corporate Taxation: The 2017 Revision (P.L. 115-97), by Jane G. Gravelle and Donald J. Marples.

Source: CRS analysis of the CARES Act (S. 3548, as Introduced).

- a. In guidance released on March 18, 2020, the U.S. Department of the Treasury announced that the tax payment deadline had been extended from April 15, 2020, to July 15, 2020. This guidance did not extend the April 15, 2020, filing deadline. See the U.S. Department of the Treasury’s March 18, 2020, press release, “Treasury and IRS Issue Guidance on Deferring Tax Payments Due to COVID-19 Outbreak,” at <https://home.treasury.gov/news/press-releases/sm948>. Subsequently, the Treasury announced via tweet that the tax filing deadline would also be moved to July 15, 2020.

Chapter 393

**OVERVIEW OF INITIAL RESPONSES TO COVID-19
BY THE ADMINISTRATIVE OFFICE OF U.S. COURTS
AND BY SELECT COURTS WITHIN THE
FEDERAL JUDICIARY***

Barry J. McMillion

This CRS Insight provides information related to initial responses to Coronavirus disease 2019, or COVID-19, by the Administrative Office of U.S. Courts and select courts within the federal judiciary. Consequently, this Insight is not intended to provide a comprehensive overview of the policies and practices adopted by each federal court or judicial entity. Additionally, given the rapidly changing situation surrounding COVID-19, the information provided in this Insight may be superseded by new information from that which is described in the text below. If there are any questions regarding whether such changes have occurred, congressional staff may contact the author of this Insight. The author can also be contacted for information related to responses to COVID-19 by other federal judicial entities or courts not specifically addressed below.

ADMINISTRATIVE OFFICE OF U.S. COURTS

The Administrative Office of U.S. Courts (AO) is the agency within the federal judiciary that provides, in part, administrative services and program support to federal courts. On March 12, 2020, the AO issued a statement indicating that federal courts were “individually coordinating with state and local health officials to obtain local information about the coronavirus (COVID-19).” The flexibility provided to federal courts to adapt to local

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11252, dated March 18, 2020.

conditions is reflective of past practices during other recent emergencies (see, for example, the response by some courts to Hurricane Sandy in 2012).

The AO also created a task force to serve “as a single point of contact to share information and guidance related to the coronavirus outbreak as it relates to the Judiciary.” The taskforce includes, in part, representatives from the General Services Administration (GSA), the U.S. Marshals Service, and Federal Occupational Health (FOH).

UNITED STATES SUPREME COURT

On March 16, 2020, the Supreme Court announced that it is postponing all oral arguments scheduled for its March session (March 23-25 and March 30-April 1). The Court also announced that the building itself will continue to be open for official business but that it is “expanding remote working capabilities” to reduce the number of on-site Court employees. Previously, on March 12, 2020, the Court announced that its building was closed to the public until further notice.

U.S. DISTRICT COURTS IN WASHINGTON STATE

The first case of COVID-19 in the United States was identified in Washington State on January 21, 2020. At present, the state has the second-highest number of confirmed cases of COVID-19 in the United States, as well as the most deaths attributable to the virus. The Western District of Washington—with courthouses in Seattle and Tacoma—announced on March 6, 2020, that most in-court civil and criminal proceedings, including jury trials, are postponed until further court order. The Eastern District of Washington (with its headquarters in Spokane) announced on March 16, 2020, that it is cancelling naturalization ceremonies through April 30, 2020.

U.S. DISTRICT COURTS IN THE FIVE MOST POPULOUS JUDICIAL DISTRICTS

According to data compiled by CRS, the five most populous federal judicial districts are, in ascending order, the Central District of California, the Middle District of Florida, the Southern District of Texas, the Northern District of Illinois, and the District of New Jersey. These five judicial districts have a combined population of approximately 59.9 million, representing approximately 18.3% of the U.S. population (based on 2018 estimates by the Census Bureau).

Some of the initial responses by these five courts are highlighted below (the [hypertext link](#) for a particular court provides additional information regarding the court’s response). The actions taken by these courts are presented as illustrative examples, and may not be representative of actions taken by other courts.

- *Central District of California* (Los Angeles, Riverside, Santa Ana): The court has restricted entry to courthouses in the district, as well as access to its probation and pretrial services offices, for any individuals who have travelled to certain countries within the past 14 days. Additionally, the court has also issued an order that no jurors would be called for criminal or civil trials until April 13, 2020.
- *Middle District of Florida* (Orlando, Tampa, Jacksonville, Fort Myers, Ocala): The court has restricted entry to courthouses in the district for certain individuals, including those who have traveled within 14 days to or from certain countries. The bankruptcy court (a unit of the district court) has announced several changes, including that all non- evidentiary hearings will be conducted by telephone.
- *Southern District of Texas* (Houston, Galveston, Laredo, Corpus Christi, Brownsville, Victoria, McAllen): The court announced that civil and criminal jury trials in two of its seven divisions (covering the Houston and Galveston areas) are deferred through May 1, 2020. The court has otherwise emphasized that “other deadlines and settings remain in place pending further order by each judge in specific cases or by standing order.”
- *Northern District of Illinois* (Chicago, Rockford): The court has postponed all civil jury trials that were scheduled to begin before April 3, 2020, and extended deadlines in all federal civil cases in the district by 21 days from their current deadline. Additionally, criminal case proceedings that cannot be postponed will be conducted in Chicago only (not Rockford) by emergency district judges. Grand juries will continue to meet during the week of March 16, 2020, but “reasonable limits” will be placed on future meetings.
- *District of New Jersey* (entire state): On March 16, 2020, the court announced visitor restrictions covering individuals who have been diagnosed with COVID-19, asked to self-quarantine, or who have had close contact with someone who has been asked to self-quarantine. Additionally, on the same date, the court announced that all civil and criminal jury selections and jury trials scheduled to begin before April 30, 2020, are postponed pending further notice. The court has also encouraged all judicial officers to conduct proceedings by telephone or videoconferencing where practicable and permitted by law.

Chapter 394

OVERSIGHT PROVISIONS IN H.R. 6074, THE CORONAVIRUS PREPAREDNESS AND RESPONSE SUPPLEMENTAL APPROPRIATIONS ACT*

Ben Wilhelm

President Donald Trump signed H.R. 6074, the Coronavirus Preparedness and Response Supplemental Appropriations Act, on March 6, 2020. It provides a total of \$8.3 billion in supplemental funding to support the response of the United States to Coronavirus Disease 2019 (COVID-19).

Prior to the passage of H.R. 6074, Congress had already begun to oversee the federal government's response to COVID-19 with committee hearings in both the House and the Senate. Other committees are planning additional hearings in the coming weeks, and the Trump Administration has also been providing regular briefings.

This voluntary flow of information among Congress, senior Administration leaders, and frontline experts will facilitate Congress's response to COVID-19. If lines of communication remain open, voluntary information sharing may prove to be sufficient to meet Congress's needs and expectations for oversight. However, H.R. 6074 makes explicit a number of requirements regarding both the type and frequency of information Congress will receive.

H.R. 6074 appropriates significant funding for specific responses to COVID-19 and sets explicit requirements regarding how funds may be spent. The specificity of these conditions, as well as ongoing development of the outbreak, make it particularly important that Congress receive information in a timely manner. Even relatively short delays may prevent Congress from ensuring that the executive branch is following its instructions. The reporting requirements in H.R. 6074 are designed to improve the executive branch's ability to provide timely information to Congress.

This Insight details the oversight provisions included in H.R. 6074. CRS has produced several other written products related to COVID-19, some of which are linked at the bottom of this Insight. All CRS materials on the subject are available on CRS.gov.

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11236, dated March 12, 2020.

CONSULTATION AND REPORTING REQUIREMENTS IN H.R. 6074

H.R. 6074 creates the following reporting requirements for entities receiving supplemental appropriations:

- Title III appropriates \$300 million to be transferred into the Infectious Disease Rapid Response Reserve Fund. If the Secretary of the Department of Health and Human Services (HHS) declares an infectious disease emergency and seeks to use the fund (as authorized by the third proviso of Section 231 of Division B of P.L. 115-245), the Secretary must, in consultation with the director of the Centers for Disease Control and Prevention, report to the Appropriations Committees every 14 days for one year from the date of the declaration “as long as such report[s] would detail obligations in excess of \$5,000,000” or upon the request of either committee.
- Title III also appropriates \$300 million to the HHS Public Health and Social Services Emergency Fund for the purchase of “vaccines, therapeutics, and diagnostics” to respond to COVID-19. In order to access these funds, the HHS Secretary must certify to the Appropriations Committees that the funds are necessary in addition to other funds appropriated in the bill.
- Section 302 authorizes the HHS Secretary to enter into personal services contracts to respond to COVID-19 following notification to the Appropriations Committees.
- Section 305 requires that the HHS Secretary provide to the Appropriations Committees a detailed spend plan for the funds appropriated to HHS no later than 30 days after enactment of the act (i.e., April 6). HHS is required to update the plan every 60 days until September 30, 2024. Each spend plan submission must also include a listing of all new contract obligations in excess of \$5 million and the amount of each of those obligations.
- Section 401 establishes that funds appropriated under Title IV of the act to the Department of State and United States Agency for International Development (USAID) are subject to the “regular notification procedures” of the Appropriations Committees. This requirement does not apply to \$300 million appropriated for International Disaster Assistance.
- Section 404 allows funds appropriated in the act for Global Health Programs and the Economic Support Fund to be contributed to international organizations following consultation with the Appropriations Committees.
- Section 406(a) requires the Secretary of State and the USAID administrator to submit a strategy to “prevent, prepare for, and respond to coronavirus abroad” to the Appropriations Committees within 15 days of the enactment of the act (i.e., March 21).
- Section 406(b) requires the Secretary of State and the USAID administrator to provide the Appropriations Committees a report on the proposed uses of appropriated funds by country and project no later than 30 days after enactment (i.e., April 6). It also requires updates every 60 days until September 30, 2022, and then every 180 days until all funds have been expended.

- Section 505 requires the comptroller general of United States to consult with the Appropriations Committees on the “oversight of activities supported with funds appropriated by this Act.”
- H.R. 6074 also includes several provisions amending existing transfer authorities and authorizing the transfer of funds between specified accounts, subject to notification of the Appropriations Committees.

SUPPLEMENTAL FUNDING FOR SELECT INSPECTORS GENERAL

A portion of the supplemental funding appropriated in H.R. 6074 is directed to the Offices of the Inspectors General for HHS and USAID. Section 306 provides for the transfer of up to \$2 million from the Public Health and Social Services Emergency Fund to the Office of the Inspector General for HHS.

The inspector general is required to consult with the Appropriations Committees prior to the obligation of funds regarding how such funds will be used.

H.R. 6074 also appropriates \$1 million to the Office of the Inspector General for USAID for the oversight of USAID activities funded by the act.

Chapter 395

H.R. 6201: PAID LEAVE AND UNEMPLOYMENT INSURANCE RESPONSES TO COVID-19*

Sarah A. Donovan, Julie M. Whittaker and Katelin P. Isaacs

ABSTRACT

This Insight provides summary information on the paid leave and unemployment insurance (UI) provisions in the House-passed version of H.R. 6201, the Families First Coronavirus Response Act, including the technical corrections made by H.Res. 904. For a general discussion of current workplace leave policies and UI programs and benefits, including considerations related to COVID-19, see CRS Insight IN11233, *Workplace Leave and Unemployment Insurance for Individuals Affected by COVID-19*. For additional legislation introduced related to UI and COVID-19, see CRS Report R45478, *Unemployment Insurance: Legislative Issues in the 116th Congress*.

PAID LEAVE PROVISIONS IN H.R. 6201

H.R. 6201, as amended by H.Res. 904 contains two paid leave provisions: (1) providing for paid family and medical leave in certain instances for needs related to a COVID-19 public health emergency and (2) providing for paid sick leave for a similar but more expansive set of needs. In terms of private-sector coverage, the provisions apply only to eligible employees who are employed by employers with fewer than 500 employees. The bill also includes tax credit provisions to help employers cover costs related to paid leave requirements; self-employed individuals, including gig workers, are similarly eligible for tax credits if they are unable to perform services in their trade or business for reasons discussed below.

Both provisions allow employers of health care providers and emergency responders to exclude such employees from the application of the leave provisions. Further, both provisions would allow the Secretary of Labor to issue regulations that (1) exclude certain health care

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. IN11249, dated March 20, 2020.

workers and emergency responders from the leave provisions and (2) exempt employers with fewer than 50 employees from the requirement to provide leave when an employee's child's school or care facility is unavailable if it "would jeopardize the viability of the business as a going concern."

Both paid leave provisions would take effect no later than 15 days after the bill's enactment and expire on December 31, 2020.

DIVISION C — EMERGENCY FAMILY AND MEDICAL LEAVE EXPANSION ACT

H.R. 6201, as amended by H.Res. 904, proposes to temporarily extend Family and Medical Leave Act (FMLA) leave to include leave needed to care for the employee's minor child whose school or care provider is unavailable due to a COVID-19 public health emergency. Such FMLA-leave may be used by employees who have been employed by their current employer for at least 30 calendar days and work for a covered employer. Covered employers are private-sector employers employing fewer than 500 employees, and certain public agencies, including state and local governments.

The first 10 days of the new FMLA leave may be unpaid; although the employee may elect to use other paid leave during that period. Employers would be required to compensate employees for the remainder of FMLA-leave taken for qualifying public health emergencies (i.e., up to 10 work weeks) at two-thirds of their regular rate of pay. Such paid leave is capped at \$200 per day and \$10,000 total per employee.

FMLA leave is generally job-protected, but this requirement would not apply to employers with fewer than 25 employees if the employee used FMLA-leave for public health needs and certain conditions are met. Whereas FMLA provides that employees may seek damages or equitable relief for FMLA violations, 6201 provides that such liability would not apply to employers with fewer than 50 employees for violations related to FMLA-leave for a public health emergency.

DIVISION E — EMERGENCY PAID SICK LEAVE ACT

The bill would require covered employers to temporarily provide paid sick leave to employees to attend to certain COVID-19-related medical and caregiving needs if the employee is unable to work (including telework). Such needs include (1) the employee's self-isolation or quarantine in compliance with an official order or as advised by a health care provider due to concerns related to COVID-19; (2) to care for an individual subject to such an order or medical advice to self-isolation or quarantine; (3) to seek a medical diagnosis when the employee is experiencing COVID-19 symptoms; (4) to care for the employee's child, generally a minor child, whose school or care provider is unavailable due to a COVID-19 public health emergency; and (5) any other substantially similar condition specified by the Secretary of Health and Human Services in consultation with the Secretary of the Treasury and the Secretary of Labor.

Full-time employees would be entitled to 80 hours of paid sick leave, and part-time employees the equivalent of 2 weeks of leave. For leave taken for the employee's quarantine, self-isolation, or medical diagnosis, sick leave is compensated at the greater of the employee's regular rate of pay, the federal minimum wage, or the minimum wage rate in the applicable state or locality of employment; such paid leave is capped at \$511 per day and \$5,110 total per employee. For caregiving and other needs, the employer must compensate the employee at two-thirds of such a rate; such paid leave is capped at \$200 per day and \$2,000 total per employee. The provisions apply broadly to public-sector employers and to private-sector employers with fewer than 500 employees.

UNEMPLOYMENT INSURANCE PROVISIONS IN H.R. 6201

The UI provisions in Division D of H.R. 6201, which were not amended by H.Res. 904, would give states more flexibility to address COVID-19 through expanded benefit eligibility as well as additional administrative funding, among other UI measures. Unlike workplace leave policies, the UI system generally treats public-sector workers similarly to private-sector workers. UI benefits replace a proportion of wages for those workers who are temporarily or permanently separated from their jobs, but are otherwise able, available, and searching for work. Depending on state law, UI benefits may replace up to 60%-66% of total wages and are often subject to a benefit cap of half of the state's average weekly wage, although some states have lower benefit caps.

DIVISION D — EMERGENCY UNEMPLOYMENT INSURANCE STABILITY AND ACCESS ACT OF 2020

The UI provisions in Division D of H.R. 6201 would

- Provide \$1 billion in “emergency administrative grants” to states in calendar year 2020 for administrative purposes. Half of this amount would be available to all states who meet certain requirements related to Unemployment Compensation eligibility notifications and claims access. The second half of this amount would be available to states that experience at least a 10% increase in UC claims over the previous calendar year and meet certain other requirements related to easing UC eligibility requirements for individuals affected by COVID-19. There would be reporting requirements to U.S. Department of Labor (DOL) and committees of jurisdiction within one year for states that receive these grants.
- Waive any federal UI requirements related to work search, one-week waiting periods, quits for good cause, and employer tax assessments for state programs (i.e., under Section 303 of the Social Security Act and Federal Unemployment Tax Act [FUTA] Section 3304) if a state modifies its UC laws “on an emergency temporary basis as needed to respond to the spread of COVID-19.”

- Temporarily waive interest payments and the accrual of interest on federal advances (loans) to states to pay UC benefits through December 2020. However, these provisions would not reduce any underlying loan principal.
- Require DOL to provide assistance to states in establishing, implementing, and improving Short-Time Compensation (work sharing) programs.
- Temporarily make Extended Benefits (EB) 100% federally financed (under permanent law: 50% state, 50% federal) from enactment until the end of December 2020, but only for states that receive emergency administrative grants. This bill would also temporarily remove the current incentive in EB law for states to have a waiting week for their regular UC programs through December 2020.

Chapter 396

TAX CREDIT FOR PAID SICK AND FAMILY LEAVE IN THE FAMILIES FIRST CORONAVIRUS RESPONSE ACT (H.R. 6201) (UPDATED)*

Molly F. Sherlock

ABSTRACT

The Families First Coronavirus Response Act (H.R. 6201) includes an employer tax credit for the paid sick and family leave required as part of this legislation. This tax credit is intended to cover the cost to businesses of providing paid leave to address the coronavirus disease (COVID-19) pandemic. This Insight provides an overview of the tax credits, including the corrections included in H.Res. 904, as passed by the House on March 16, 2020.

TAX CREDITS FOR PAID LEAVE

The employer payroll tax credit is for wages paid to fulfill the new leave requirements. The Emergency Paid Sick Leave Act, Division E of H.R. 6201 as modified by H.Res. 904, generally requires private employers with fewer than 500 employees, and all government employers, to provide employees with two workweeks of paid sick leave for certain coronavirus-related leave purposes. The Emergency Family and Medical Leave Expansion Act, Division C of H.R. 6201, as modified by H.Res. 904, generally provides employees of private employers with fewer than 500 employees, state and local government employees, and some federal employees expanded job-protected Family and Medical Leave Act (FMLA) leave for certain caregiving responsibilities. Under certain conditions, this expanded family leave must be partially compensated by employers. For both sick and family leave, the bill

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. IN11243, dated March 17, 2020.

includes provisions that may exclude health care providers, emergency responders, and employees in certain small businesses from leave requirements.

The legislation expands access to paid sick and family leave for employees at many small- and mid-sized businesses. Employees of large businesses, however, would not have guaranteed access to paid sick or family leave under this proposal.

Employer Payroll Tax Credit

The employer payroll tax credit is computed using wages paid, and claimed against the employer's share of the Social Security or railroad retirement payroll tax in each calendar quarter. The Social Security payroll tax rate is generally 12.4% of wages, with 6.2% paid by employers and 6.2% paid by employees. The Social Security payroll tax applies to workers' earnings up to an annual limit, \$137,700 in 2020.

Similar taxes are withheld for railroad employees. The Social Security trust fund will not be affected by the tax credit. A general fund transfer to the trust fund will offset the reduction in federal revenues from the tax credit.

The tax credit is refundable. If an employer's tax credits exceed its payroll tax liability, the excess can be received as a payment from the Treasury. Employers that claim this credit are required to include the amount claimed in gross income, for income tax purposes, offsetting the reduction in gross income from deducting wages paid (preventing a double benefit). Additionally, employers cannot claim this credit for any wages taken into account for the purposes of calculating the employer tax credit for paid family and medical leave. Employers may also elect not to have the credit apply. The credit does not apply to state or local governments. The tax credits can be claimed for a period to begin within 15 days following enactment, and ending December 31, 2020.

Sick Leave

Employers can claim a tax credit for 100% of the amount required to be paid in sick leave wages. Sick leave wages must be paid for up to 10 workdays for a full-time employee (prorated for part-time employees). The maximum amount that must be paid in sick leave depends on the purpose for which the sick leave is taken.

Sick leave wages cannot exceed \$511 per day for employees if they are taking leave because (1) the employee is subject to a federal, state, or local quarantine or isolation order related to COVID-19; (2) the employee has been advised by a health care provider to self-quarantine due to COVID-19; or (3) the employee is experiencing symptoms of COVID-19 and is seeking a medical diagnosis.

Sick leave wages cannot exceed \$200 per day for employees if they are taking leave because (A) the employee is caring for an individual described in number (1) or (2) above; (B) the employee is caring for their own minor child whose school, place of care, or caregiver is closed or unavailable due to COVID- 19; or (C) the employee is experiencing any other to-be-specified "substantially similar condition." The tax credit amounts for paid sick leave can be increased by the amount employers pay for an employee's health care plan while they are on leave.

Family Leave

The employer tax credit is for paid family leave, required for employees who take leave (are unable to work) because they must care for their own minor child whose school or place of care has been closed due to a COVID-19-related public health emergency.

The paid leave period for the purposes of the tax credit begins once an individual has taken 10 days of leave for the family leave purpose described above. These 10 days of leave may consist of unpaid leave, or an employee may elect to use paid vacation, personal, or another form of paid leave. After this 10-day period, employees will receive a benefit from their employers that is at least two-thirds of the employee's usual pay, but not more than \$200 per day. The tax credit for family leave wages is limited to \$200 per day, and \$10,000 total per employee. The tax credit amounts for paid family leave can be increased by the amount employers pay for an employee's health care plan while they are on leave.

TAX CREDIT FOR SELF-EMPLOYED INDIVIDUALS

Self-employed individuals, including gig workers, are eligible for tax credits similar to above. If individuals are unable to perform services in their trade or business for the sick leave purposes described above, the individual may qualify for an income tax credit equal to 100% of average daily self-employment income. Like the employer credits, this credit is limited to \$511 per day for certain qualifying sick leave purposes, and \$200 for other sick and qualified family leave purposes. The sick leave credit is limited to a maximum of 10 days. The family leave credit is limited to 50 days. For self-employed individuals, the income tax credit is refundable (meaning that if the tax credit amount exceeds the individual's income tax liability, the excess is received as a refund, or payment, from the Treasury). Like the employer tax credit, the tax credits for self-employed taxpayers can be claimed for a period to begin within 15 days of enactment, and ending December 31, 2020.

ISSUES AND CONSIDERATIONS FOR CONGRESS

The tax credit for required paid sick and family leave will largely offset the cost of providing such required leave in the Families First Coronavirus Response Act. The legislation mandates leave for employees of private-sector firms that employ fewer than 500 individuals. In 2019, 47.6% of employees worked in firms with fewer than 500 employees. The other 52.4% of employees worked in large firms, or firms with 500 or more employees. This legislation does not mandate sick leave for employees of these firms who may not have access to paid sick or family leave. Nor does it provide tax credits for these larger firms for providing leave. Some experts have expressed concern about this potential gap in coverage.

A refundable payroll tax credit will likely reduce the financial burden of providing required paid sick and family leave. The credit, however, does not necessarily encourage businesses to provide additional leave beyond what is required. Employees of large businesses in particular may be left without coverage.

Additionally, this credit is not designed to help businesses who have suffered lost business as a result of COVID-19.

Chapter 397

WORKPLACE LEAVE AND UNEMPLOYMENT INSURANCE FOR INDIVIDUALS AFFECTED BY COVID-19*

Julie M. Whittaker, Sarah A. Donovan and Katelin P. Isaacs

ABSTRACT

This Insight provides a brief overview of the current availability of job-connected assistance to individuals, which may be relevant to the outbreak of coronavirus disease 2019 (COVID-19).

Specifically, this product discusses workplace leave, paid and unpaid, that may be available to workers affected by the virus, as well as unemployment insurance (UI) benefits. It also discusses policy options to amend or expand existing UI programs to be more responsive to the effects of COVID-19.

WORKPLACE LEAVE

Workers affected by COVID-19 may seek to use paid or unpaid workplace leave for their own medical needs or to care for family members. Leave, even if unpaid, may be preferable to a complete separation from employment if it allows for continuation of health care benefits and facilitates the employee's return to work following recovery. Most federal civil service employees are entitled to paid sick and annual leave, but no federal law requires private-sector employers to provide paid leave of any kind.

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. IN11233, dated March 16, 2020.

Family and Medical Leave Act

The Family and Medical Leave Act (FMLA) provides an entitlement to eligible workers to unpaid, job-protected leave for a limited set of family caregiving and medical needs, with continued group health plan coverage; eligible employees may use up to 12-workweeks of leave in a 12-month period. FMLA coverage and eligibility is not universal. Federal, state, and local governments are covered employers, but private-sector employers employing fewer than 50 employees are not. Employees of covered employers must also meet tenure, hours-of-service, and work-site coverage requirements before using FMLA-leave. No other federal law creates a leave entitlement for private-sector workers.

FMLA and COVID-19 Considerations

A key consideration is whether FMLA-leave can be claimed for COVID-19-related needs, such as testing, quarantine, treatment, and caregiving. In most instances, FMLA-leave for medical needs (the employee's own or a family member's) is limited to *serious health conditions*, which require overnight inpatient care or *continuing treatment* by a health care provider. Continuing treatment generally constitutes several days of incapacitation and multiple in-person treatments by a health care provider; a single in-person treatment may suffice if the employee is prescribed a regimen of continuing treatment (e.g., prescription medication). As such, hospitalization and, potentially, testing for COVID-19 may be FMLA-qualifying needs. However, a worker who tests positive for the virus and is sent home to rest and take over-the-counter medications is unlikely to qualify for FMLA-leave for the period of home recovery. Federal law and regulations do not provide for FMLA-leave to address general needs related to public health emergencies (e.g., school closures).

State Leave and Leave Insurance Laws

Some states have enacted family and medical leave laws (similar to FMLA) that entitle workers to unpaid leave in certain instances. In addition, five states currently operate state leave insurance programs, which provide cash benefits (a percentage of the employee's usual earnings, up to a maximum amount) to eligible workers who are absent from work for certain medical and caregiving reasons. As with FMLA, the extent to which state leave entitlements and leave insurance benefits may be claimed by COVID-19-affected workers will depend upon the worker meeting the criteria set out in state law.

Some states have paid sick leave or paid time-off laws that require covered employers to allow employees to accrue and use several days of leave per year. Paid sick leave can generally be used for the employee's own medical needs or to attend to the medical needs of certain family members. Some states, like New Jersey, allow that accrued sick leave may be used for workplace or school closures due to a public health emergency or because a public health official has determined that the employee should be quarantined.

Policy Options

As noted, the extent to which employees may use FMLA-leave for COVID-19 related needs is limited and must be assessed on a case-by-case basis. Congress may consider expanding FMLA-qualifying needs to include those related to a declared public health emergency or expanding the act's employer coverage (e.g., including some employers with fewer than 50 employees). Given the likelihood that such changes will complicate employers' scheduling and otherwise disrupt business activity, Congress may also consider pairing them with employer assistance (e.g., through state grants or tax credits to help cover the costs of hiring replacements for workers on leave).

THE FEDERAL-STATE UNEMPLOYMENT INSURANCE SYSTEM

Two programs within the federal-state unemployment insurance (UI) system may either respond to some types of unemployment caused by COVID-19 or could be modified to respond more broadly to provide weekly income replacement for individuals unavailable to work or unemployed as a result of COVID-19. Unlike workplace leave, the UI system generally treats public-sector workers similarly to private-sector workers. The National Association of State Workforce Agencies (NASWA) has published information provided by states on how they are dealing with workforce issues related to the impact of COVID-19 on their daily operations.

Unemployment Compensation

The joint federal-state Unemployment Compensation (UC) program provides income support through weekly UC benefit payments. Although there are broad requirements under federal law regarding UC benefits and financing, the specifics are set out under each state's laws. States administer state-funded UC benefits with U.S. Department of Labor (DOL) oversight, resulting in 53 different UC programs operated in the states, the District of Columbia, Puerto Rico, and the Virgin Islands.

To receive UC benefits, claimants must generally have been laid off through no fault of their own; have enough recent earnings (distributed over a specified period) to meet their state's requirements; and be able, available, and actively searching for work. The UC program generally does not provide UC benefits to the self-employed, those who are unable or unavailable to work, or those who do not have a recent earnings history.

UC and COVID-19 Considerations

Individuals who are laid off for COVID-19-related reasons would be subject to UC laws regarding benefit eligibility in the state where the previous work was performed. As described above, some categories of workers would not meet state eligibility requirements for UC benefits. Additionally, individuals who are unavailable for work due to COVID-19—whether they are quarantined or caregiving for sick or quarantined family members—may be ineligible for UC benefits because they may not meet state requirements regarding being able

and available for work. The DOL has recently issued guidance to states on how states may be able to interpret or alter state UC eligibility requirements to broaden these definitions if they choose to do so.

Disaster Unemployment Assistance

Disaster Unemployment Assistance (DUA), which is authorized under the Robert T. Stafford Disaster Relief and Emergency Assistance Act (the Stafford Act), provides federally funded unemployment benefits to individuals unable to work as a result of a federally declared major disaster and otherwise ineligible for regular UC benefits. For example, DUA benefits may be available to the self-employed and workers unable to reach their place of employment as a direct result of a major disaster, among other categories of DUA eligible employees.

DUA and COVID-19 Considerations

The current law definition of *major disaster* for the purposes of DUA, however, does not include a disease outbreak or other public health emergency. (No public health incident has ever been declared as “major disaster” under the Stafford Act.) Therefore, DUA benefits would not be available in response to unemployment or unavailability for employment related to COVID-19.

UI POLICY OPTIONS TO RESPOND TO COVID-19

Unlike some other federal or state programs, UC and DUA have the ability to rapidly respond and provide immediate income support. Thus, Congress may consider amending or expanding current unemployment benefits for individuals affected by COVID-19. For example, the DUA authority under the Stafford Act could be a model for responding to public health emergencies. More generally, in response to the 2007-2009 recession, UC benefits were temporarily augmented and extended, with some costs temporarily assumed by the federal government. For summaries of introduced COVID-19 UI legislation, see CRS Report R45478, *Unemployment Insurance: Legislative Issues in the 116th Congress*.

Chapter 398

COVID-19: SOCIAL INSURANCE AND OTHER INCOME-SUPPORT OPTIONS FOR THOSE UNABLE TO WORK*

***Laura Haltzel, Katelin P. Isaacs, William R. Morton,
Elizabeth A. Myers, Scott D. Szymendera and Julie M. Whittaker***

OVERVIEW

There is uncertainty about how the Coronavirus Disease 2019 (COVID-19) may spread in the United States; what measures federal, state, or local governments may take to mitigate the spread; and the possible effect on individual income security from both. This In Focus provides an overview of existing federal and state government social insurance programs or options that may be implemented relatively quickly to provide financial assistance for those unable to work due to COVID-19 from (1) their own illness; (2) exposure leading to quarantine; (3) illness of a close family member or school closures that may require long-term caregiving; or (4) unemployment resulting from business closures.

EXISTING SOCIAL INSURANCE PROGRAMS

Unemployment Compensation and Disaster Unemployment Assistance

The joint federal-state Unemployment Compensation (UC) program provides income support through UC benefit payments. Although there are broad requirements under federal law regarding UC benefits and financing, the specifics are set out under each state's laws. States administer state-funded UC benefits with U.S. Department of Labor (DOL) oversight,

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IF11447, updated March 17, 2020.

resulting in 53 different UC programs operated in the states, the District of Columbia, Puerto Rico, and the Virgin Islands. To receive UC benefits, claimants must generally have been laid off through no fault of their own; have enough recent earnings (distributed over a specified period) to meet their state's earnings requirements; and be able, available, and actively searching for work. The UC program generally does not provide UC benefits to the self-employed, those who are unable or unavailable to work, or those who do not have a recent earnings history. Individuals who are laid off for reasons related to COVID-19 would be subject to UC laws regarding benefit eligibility in the state where the previous work was performed. Individuals who are unavailable for work due to COVID-19 (e.g., because of a quarantine, or caregiving for sick or quarantined family members) may not meet state requirements regarding being able and available for work.

Disaster Unemployment Assistance (DUA) provides federally funded unemployment benefits to individuals who are unable to work as a result of a federally declared disaster and are otherwise ineligible for regular UC benefits; however, the current statutory definition of "major disaster" (42 U.S.C. § 5122[2]) for the purposes of DUA does not include a disease outbreak. Thus, DUA will not be available under current law in response to COVID-19.

Unlike some federal or state programs, UC and DUA have the ability to rapidly respond and provide immediate income support. Thus, Congress may consider amending or expanding current unemployment benefits for individuals unemployed due to COVID-19. For example, the DUA authority could be a model for responding to public health emergencies. More generally, in response to the 2007-2009 recession, UC benefits were temporarily augmented and extended, with some costs temporarily assumed by the federal government.

Workers' Compensation

Every state has a workers' compensation system that provides wage-replacement and medical benefits to persons who are injured, become ill, or die in the course of employment. There is no federal requirement that states have workers' compensation systems and no federal oversight of state workers' compensation systems. The federal government administers workers' compensation for federal employees under the Federal Employees' Compensation Act (FECA) and for longshore and harbor workers and several other groups of private-sector employees, such as overseas federal contractors, under the Longshore and Harbor Workers' Compensation Act (LHWCA).

Although the state programs and the FECA and LHWCA programs share similar features, each program operates under its own laws and regulations. However, nearly all private-sector workers in the United States are covered by some form of workers' compensation. Coverage of self-employed individuals and certain other classes of workers varies by program. The diffuse nature of workers' compensation makes it difficult to provide general information on how any given program would respond to cases of workers contracting COVID-19 in the workplace.

A worker who contracts COVID-19 as a direct result of his or her job, such as a healthcare worker who contracts COVID-19 after treating a patient, would likely be covered by workers' compensation and eligible for benefits.

However, a person who contracts COVID-19 through casual contact with a coworker or other person that happens to occur in the workplace may not be covered, as it could be argued that the risk of this person being exposed to COVID-19 was not related to, or peculiar to, the individual's job. Ultimately, such compensation decisions would have to be made by the specific workers' compensation programs and may vary across programs. Workers' compensation would not generally be expected to provide any benefits to a person who is unable to work because of a quarantine order unrelated to his or her employment.

State Temporary Disability Insurance and Medical Leave Insurance

Temporary Disability Insurance (TDI) and Medical Leave Insurance (MLI) are state-mandated insurance programs that provide time-limited cash benefits to qualified workers who generally are unable to work due to *nonoccupational* illnesses or injuries. Workers qualify for benefits by meeting minimum work or earnings requirements and, in most cases, by serving a nonpayable waiting period (usually one week). Benefits replace between 50% and 90% of a worker's pre-disability earnings (up to a maximum amount) and are provided for up to 12-52 weeks. Where available, state TDI/MLI programs cover nearly all private-sector workers and, in some cases, state and local government workers. Federal workers are not covered by TDI/MLI, and self-employed individuals may elect coverage in some states. Currently, TDI/MLI programs operate only in California, Hawaii, New Jersey, New York, Puerto Rico, Rhode Island, and Washington State.

In general, covered workers who meet the state's minimum work or earnings requirements (i.e., insured workers) qualify for TDI/MLI benefits if they become unable to work due to COVID-19 illness and satisfy the waiting period requirement (if any). However, insured workers who are quarantined due to COVID-19 but who are not ill may not qualify for TDI/MLI benefits unless the state specifically permits them to do so. Historically, the federal government has played no direct role in the operation of TDI/MLI programs, which are established and funded via state laws. That said, federal law permits states to withdraw *employee* contributions (if any) from the state's unemployment fund to finance TDI/MLI benefits. Congress could permit states to use *employer* UC contributions to finance benefits; however, this option would likely assist only those states with existing TDI/MLI programs.

OTHER INCOME SUPPORT OPTIONS

Access to Individual Retirement Accounts and Employer-Sponsored Defined Contribution Pensions

The Internal Revenue Code generally imposes a 10% penalty on retirement savings account withdrawals, including those from individual retirement accounts (IRAs) and employer-sponsored defined contribution plans (such as 401[k]s and the federal government's Thrift Savings Plan), that occur before the account owner reaches age 59½.

Under current law, certain circumstances that warrant withdrawals are exempted from the penalty, including unreimbursed medical expenses in excess of 7.5% of adjusted gross income (10% if under age 65).

While individuals may withdraw amounts from their IRAs for any reason, individuals with employer-sponsored plans are generally not permitted to withdraw funds except in the case of hardship. Plans may, but are not required to, offer hardship distributions and may choose which situations qualify. Safe harbor regulations automatically deem certain expenses as being due to hardship, or immediate and heavy financial need (26 C.F.R. §1.401[k]-1[d][3][B]), including certain medical expenses and expenses and losses incurred by the employee on account of a federally declared disaster.

Internal Revenue Service guidance could clarify whether COVID-19-related expenses (outside of direct health expenses) would be included as being withdrawn on account of hardship. Hardship distributions are subject to the 10% penalty unless they qualify for an exemption. In addition, some employer-sponsored plans permit employees to take out loans (up to a statutory maximum) from their retirement accounts.

In response to certain past federally declared disasters, Congress has waived the 10% penalty for withdrawals for disaster-related expenses. For example, a provision in Division Q of the Further Consolidated Appropriations Act, 2020 (P.L. 116-94) allowed for penalty-free distributions up to \$100,000 for individuals who lived in an area that had a major federally declared disaster from January 1, 2018, to 60 days after the enactment of the legislation on December 20, 2019. Congress could enact a similar penalty waiver provision, providing penalty relief for COVID-19-related retirement account withdrawals. In 2019, 36% of U.S. households had an IRA and 43% of civilian workers participated in an employer-sponsored defined contribution retirement plan.

Chapter 399

COVID-19 ECONOMIC STIMULUS: BUSINESS PAYROLL TAX CUTS*

Molly F. Sherlock and Donald J. Marples

The economic fallout from coronavirus disease (COVID-19) has accelerated rapidly. Policymakers continue to evaluate tax policy economic relief options. Payroll tax cuts for businesses are one option that would provide economic assistance to business activities.

BUSINESS PAYROLL TAXES

Payroll taxes are collected to finance certain entitlement programs, including Social Security, parts of Medicare, and Unemployment Compensation (UC). Social Security's old age, survivors, and disability insurance (OASDI) payroll tax is paid by both employers and employees, and it finances the Social Security trust funds. The tax equals 6.2% of wages on the taxable earnings base (\$137,700 in 2020). This tax is paid by both employers and employees (with self-employed individuals paying both the employer and the employee share, or 12.4%). The primary source of funding for Medicare Part A is a separate payroll tax paid by employers and employees. Each pays a tax of 1.45% on the employee's earnings; the self-employed pay 2.9%.

Employers typically deposit payroll taxes with the Internal Revenue Service semiweekly or monthly, and report employment taxes paid on quarterly federal tax returns filed no later than 30 days after the end of the calendar quarter. Some employers with small payrolls may file annually.

Employment payroll taxes generally are paid by all types of employers: businesses, nonprofits, and government employers. Thus, tax relief that is provided through payroll tax reductions may be available to nonprofits, which generally do not benefit from income tax reductions.

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11260, dated March 20, 2020.

If maintaining Social Security or Medicare Part A trust fund balances is a policy objective, these funds can be made whole through a transfer of general revenue. In this case, the revenue loss from a payroll tax cut would add to the deficit, but not decrease amounts available for Social Security or Medicare benefits. Temporary cuts to payroll taxes enacted in past recessions have protected trust funds from any impact in such a manner.

OPTIONS FOR PAYROLL TAX CUTS

There are a number of options for how to structure and implement payroll tax reductions. The Relief for Individuals, Families, and Businesses portion (i.e., Division B) of the Coronavirus Aid, Relief, and Economic Security (CARES) Act (S. 3548) proposes a payroll tax deferral for employers. Employers and self-employed individuals would be able to defer, or postpone, the employer share of the Social Security payroll tax. Deferred tax liability would be paid in two installments: one due by December 31, 2021, and the second by December 31, 2022. The Social Security trust funds would not be affected.

Another option is to provide a payroll tax rebate. This option would return 2020 payroll taxes already paid by employers. It could be targeted to small businesses, with small businesses identified using an employee threshold, a gross receipts threshold, or some other measure. A rebate could be capped at a fixed amount per employee, or given for a certain number of employees. A payroll tax rebate could also apply only to businesses who have been ordered by federal, state, or local government officials to cease operations due to COVID-19, or these types of businesses could be given a larger rebate. A payroll tax rebate payment could improve cash flow, helping businesses with limited financial resources. Depending on how the policy was designed, a portion of the lost federal revenue may also support employers whose business activities were unaffected by the COVID-19 economic shock.

A third option is to suspend business payroll taxes (provide a payroll tax holiday). The Trump Administration has expressed interest in this option. The business community has also expressed support for a payroll tax suspension. How long the payroll tax would be suspended is one policy choice. It could be suspended for three months, for the rest of the year, or for some other period of time. There is also the question of whether employee payroll tax collections would be suspended entirely or instead reduced by some amount (e.g., reduced by two percentage points). Suspending payroll taxes would reduce the cost of keeping employees on the payroll, and thus could promote worker retention. A payroll tax suspension only helps employers with paid employees; if an employer has already been forced to lay off its workforce, a payroll tax suspension will not provide financial assistance.

PAST EXPERIENCE AND POTENTIAL EFFECTIVENESS

Employer payroll tax cuts have been enacted in the past. The Hiring Incentives to Restore Employment (HIRE) Act of 2010 (P.L. 111-147), enacted during the Great Recession, suspended the employer's share of the 2010 payroll tax (6.2% of the worker's earnings) for qualified workers (generally unemployed individuals) hired between February 3, 2010, and January 1, 2011. The policy was estimated to reduce federal revenue by \$7.6 billion. One

difference between the past policy and the current proposals is that the past policy was intended to spur hiring; current proposals have the goal of preventing layoffs.

The provision's effectiveness will depend on how the additional cash flow is utilized. According to CBO models run during the Great Recession, an employer payroll tax reduction would provide a small incentive to increase employment or hours worked. The empirical literature generally agrees with the results from the CBO model, finding that during economic turmoil businesses are prone to favor holding cash or reducing debt over making investments (Eisfeldt and Muir 2016, Bolton, Chen and Wang 2013, and Dobridge 2016). The last study also found that the use of refunds to improve a firm's cash flow reduced the firm's bankruptcy risk and the probability of a future credit-ratings downgrade. One caveat to this empirical literature is that those studies examined a different cash flow incentive—net operating loss carrybacks—that would be equivalent to a payroll tax refund.

Chapter 400

TAX CUTS AND ECONOMIC STIMULUS: HOW EFFECTIVE ARE THE ALTERNATIVES?*

Jane G. Gravelle

SUMMARY

The economic effects of the COVID-19 pandemic may lead Congress to consider a general fiscal stimulus in the form of tax cuts. This report discusses tax cuts enacted during the previous recessions and their potential effectiveness.

In response to the Great Recession several types of tax cuts were debated as possible fiscal stimulus bills—with fiscal stimulus legislation enacted in February, 2008 (P.L. 110-185) and a much larger one in February 2009 (P.L. 111-5). Both bills included individual tax cuts aimed at lower- and middle-income individuals, along with business tax cuts. In December 2010, along with an extension of expiring tax cuts, a temporary payroll tax cut was adopted. Many, but not all, tax cuts that were expiring after 2012 were extended permanently.

A tax cut is more effective the greater the fraction of it that is spent. Empirical evidence suggests individual tax cuts will be more likely to be spent if they go to lower-income individuals, making the tax rebate for lower-income individuals likely more effective than several other tax cuts. There is some weak evidence that tax cuts received in a lump sum will have a smaller stimulative effect than those reflected in paychecks, but this evidence is uncertain. However, studies of the 2001 rebate found that a significant amount of that rebate was spent. While temporary individual tax cuts likely have smaller effects than permanent ones, temporary cuts contingent on spending (such as temporary investment subsidies or a sales tax holiday) are likely more effective than permanent cuts. (Sales tax holidays may, however, be very difficult to implement.) The effect of business tax cuts is uncertain, but likely small for tax cuts whose main effects are through cash flow.

* This is an edited, reformatted and augmented version of a Congressional Research Service publication RS21126, prepared for Members and Committees of Congress dated March 18, 2020.

The economic effects of the COVID-19 pandemic may lead Congress to consider a general fiscal stimulus in the form of tax cuts. This report discusses tax cuts enacted during the previous recessions and their potential effectiveness.

Several tax cuts were discussed during consideration of fiscal stimulus in response to the Great Recession, and the specific proposal (the American Recovery and Reinvestment Act of 2009, P.L. 111-5). This stimulus as enacted included individual tax cuts directed at lower- and middle-income individuals and also included business tax cuts.

An earlier fiscal stimulus (P.L. 110-185) adopted in February 2008 included rebates and accelerated depreciation (bonus depreciation) for businesses. Some of these types of provisions were included in stimulus tax cut legislation in 2001-2003 and some of the debate centered on the effectiveness of alternatives. Among the tax cuts discussed in 2001 were tax rebates targeted towards lower-income individuals, a speed-up tax rate reductions for higher income individuals, a temporary sales tax holiday, a temporary payroll tax holiday, a temporary investment stimulus, corporate tax cuts (primarily repealing the alternative minimum tax), and dividend reductions. The 2001 tax cut included a rebate and the final version of the 2002 tax cut bill included a temporary investment stimulus. President Bush proposed accelerated rate cuts and dividend relief in his stimulus package for 2003. Proposals such as rebates were made by Democratic leaders. Although the economy recovered from the recession, issues of fiscal stimulus arose again in the 109th Congress in the wake of Hurricane Katrina. The tax stimulus enacted in response included rebates for both low and middle income individuals and temporary bonus depreciation for businesses.

In February of 2009, Congress passed a much larger package (P.L. 111-5), which included spending and tax cuts. Among tax cuts the single largest provision was a two-year refundable earnings credit, the making-work-pay credit, with a dollar cap that was provided through a change in withholding rather than a rebate. Other tax components target lower-income individuals and businesses. The business provisions included a bonus depreciation extension and a carryback of net operating losses. The legislation also extended the Alternative Minimum Tax, which tends to go to higher-income individuals.

In December of 2010, along with extending expiring tax cuts (which tended to benefit middle- and higher-income individuals) and unemployment benefits, P.L. 111-312 adopted a temporary two-percentage-point reduction in the payroll tax. As with the making-work-pay credit, its benefits were received in paychecks over time, and unlike the rebate or making-work-pay credit, was not targeted to lower- and middle-income families. Many, but not all, tax cuts that were expiring after 2012 were extended permanently. The payroll tax was not extended, and bonus depreciation was extended for a year.

Effectiveness of a tax cut for short run stimulus purposes is judged by the extent to which the tax cut increases private demand (either consumption or investment spending). A tax cut that is saved will have no short term stimulative economic effect (or long term one, if the cut is financed by a deficit, since increased private saving would be offset by decreased government saving). Thus, in general, tax cuts received by individuals will not be successful as a short run stimulus if they lead to additional saving, and tax cuts received by firms will not be successful unless they lead to spending on investment (or lead quickly to spending on consumption by shareholders).

The following four propositions can generally be supported by economic theory and empirical evidence:

- (1) Individual income tax cuts directed at lower-income individuals will likely have a larger effect than cuts directed at higher income individuals, other things equal. This distributional effect suggests that the most effective tax cut would be a rebate which is not only a flat amount but specifically directed at lower-income individuals (who did not have tax liability). While payroll and sales taxes are more concentrated among lower- and moderate-income individuals than the normal income tax, they are largely proportional taxes and the bulk of them will still go to middle- and higher-income individuals. Most income tax cuts actually exclude the bottom 44% of the population who do not pay income tax unless they are refundable (as with the February 2008 cut). Similarly, payroll tax cuts exclude 16% of the population who do not pay payroll taxes.¹ Tax reductions enacted in 2001 were concentrated among the upper part of the income distribution as are dividend and capital gains tax reduction. A flat dollar reduction, if refundable, would be more concentrated on lower and middle incomes than tax cuts that reduce rates or allow deductions.
- (2) There is weak empirical evidence that a lump sum tax cut is less likely to be spent than one received in small increments (e.g. through withholding). This effect could make a rebate less effective than alternative individual tax cuts if it were not for the distributional evidence. However, the distributional effect is more solidly grounded in economic theory, and is based on more concrete and extensive empirical evidence.
- (3) Certain types of temporary tax cuts are likely to be more effective than permanent ones while, in other cases, they are less effective. The most important illustration of this effect is a temporary investment subsidy, but it could also apply to a temporary sales tax holiday or any design where spending is required to obtain the subsidy and is for a limited duration. Otherwise, temporary cuts are likely to be less effective than permanent ones.
- (4) Corporate tax cuts that do not make new investments more profitable are unlikely to have much effect on investment or consumer spending, especially when the economy is in a recession, and the effect of corporate rate cuts is likely small.

The remainder of this report provides a summary of the evidence and economic reasoning supporting these propositions. Before discussing these propositions, however, it is important to note the differences between a model where individuals consume based primarily on current income compared to those where individuals consume primarily out of permanent (lifetime) income, because much of the empirical analysis focuses on this issue. Optimal lifetime consumption models imply that consumption is based on permanent income and suggest very little will be spent out of transitory income (because it has little effect on permanent income). Thus, a temporary tax cut, which is the normal mode of a fiscal stimulus, would be ineffective. Extensive empirical investigation has rejected this permanent income model in its pure form and suggests that consumption responds to permanent and current income.

¹ Philip Stallworth and Daniel Berger, "The TCJA Is Increasing The Share Of Households Paying No Federal Income Tax, Tax Policy Center," September 5, 2018, <https://www.taxpolicycenter.org/taxvox/tcja-increasing-share-households-paying-no-federal-income-tax>.

Proposition 1: A tax cut directed at lower-income individuals should have a larger effect on spending than one directed at higher-income individuals.

Data show that the fraction of income saved rises as income rises.² One study found that the savings rate for the top 1% was at least 300 times the average.³ Arraying families by wealth, another study found that the top 1% saved 37%, the next 9% saved 15%, and the bottom 90% saved 0%.⁴

This pattern is far too pronounced to be accounted for by business cycle reasons and cannot be explained by life cycle patterns and thus, itself implies a departure from the permanent income model of consumption.⁵ A saving rate that rises across incomes could be expected even in a permanent income model if each individual has the same permanent saving rate. At any time, some individuals may be earning lower than average amounts and others higher than average amounts. Thus the transitory income would understate permanent income in some cases and overstate it in others. Since more individuals with unusually low incomes would fall into the lower groups (and more with higher incomes into the high groups), some pattern of rising saving rates is expected. But empirically the effect is far too large to be explained by this phenomenon (which can be examined by looking at variations over time for an individual). A rising saving share with income could also arise from life cycle reasons. Typically income is low in the early years of life, rises during the working career and falls at retirement. If individuals want consumption to be smoother than income, they will save less when they are young and old and have lower incomes, and save more in the middle when they have higher incomes. However, when examining the data, we find that age does very little to explain saving behavior and the patterns of rising saving rates with income persist within age groups.

Aside from these empirical observations, there are theoretical reasons to expect that lower income individuals are likely to spend more of an additional dollar of income than do higher income individuals, especially in the case of a temporary tax cut, which is the kind of cut normally associated with fiscal stimulus. They may have a lower-lifetime saving rate because social welfare programs are likely to have a higher wage replacement rate during instances of bad luck (e.g. disability) or old age and because they are less likely to wish to leave bequests. Indeed, for some means-tested programs, assets can disqualify an individual from coverage. They may have less information with which to optimize over time and, if they save at all, simply have a target amount (at least in the short run), so that additional income is spent (including temporary income increases). Finally, they are more likely to be subject to

² This pattern can be found in data from the Bureau of Labor Statistics, Consumer Expenditure Survey, <https://www.bls.gov/cex/2018/combined/decile.pdf>, although there are a number of concerns about measurement in this survey, especially with respect to capturing high incomes or capturing all income. The bottom 10% had a negative savings rate of 4.3% and the second 10% had a 2.8% saving rate, whereas the top 10% had a 24.6% saving rate.

⁵ See Martin Browning and Annamaria Lusardi, "Household Savings: Micro Theories and Micro Facts," *Journal of Economic Literature*, vol. 34 (December 1996); and John Sabelhaus and Jeff Groen, *Can Permanent Income Theory Explain Cross Section Consumption Patterns?*, Congressional Budget Office, Technical Paper 1997-3, July 1997. The general view that incentives directed at low-income individuals are more effective is reflected in different multipliers used by macroeconomic forecasters, as discussed in CRS Report R45780, *Fiscal Policy Considerations for the Next Recession*, by Mark P. Keightley.

liquidity constraints; that is, to prefer to spend more than their earnings and not be able to because they cannot borrow and have no assets. Indeed, permanent income theories suggest that for a temporary tax cut, tax cuts for non-liquidity constrained individuals may have virtually no effect, while tax cuts for liquidity constrained individuals will be largely spent.⁶

Proposition 2. A tax cut provided through a lump sum payment may be less likely to be spent than one which shows up in withholding, but the evidence is weak.

This differential effect (which would not occur in a permanent income model) was pointed out by the Congressional Budget Office (CBO) in its studies of the effectiveness of alternative tax cuts.⁷ CBO referred to a comparison of results from two studies that examined the effect of income tax refunds, and of expected rate cuts from pre-announced tax cuts of the early 1980s.⁸ Both studies rejected the permanent income model (suggesting some spending effects from a transitory tax cut), but larger effects were found for the rate reductions.

There are, however, two reservations about comparing these two events to gain insight into the effects of lump-sum tax cuts versus tax cuts reflected in paychecks over time. First, to the extent that individuals use over-withholding as a means of forcing themselves to save, one

⁶ An extensive literature has addressed these issues. They are related to the empirical rejection, by and large, that consumption is solely determined by permanent income, as occurs with rational, optimizing models of consumer behavior in perfect capital markets (as reviewed in Browning and Lusardi, cited above). These empirical tests generally find a smaller marginal propensity to consume than is indicated by long run, economy-wide savings rates, but nevertheless one far above zero. Some economists have suggested that heterogeneity among consumers is responsible, that is, that some individuals behave according to the rational optimizing model, while the consumption of others is closely affected by current income. There is evidence that liquidity constraints play an important role. In addition to the review in Brown and Lusardi, above, see N. Gregory Mankiw, "The Savers-Spenders Theory of Fiscal Policy," *American Economic Review*, vol. 90 (May 2000), pp. 120-125 for a review and an additional paper that finds support for liquidity constraint effects: Jonathan McCarthy, "Imperfect Insurance and Differing Propensities to Consume Across Individuals," *Journal of Monetary Economics*, vol. 36 (November 1995), pp. 301-327. However, positive results are not universally found including results in several recent studies (Nicholas Souleles, "The Response of Household Consumption to Income Tax Refunds," and Jonathan Parker, "The Reaction of Household Consumption to Predictable Changes in Social Security Taxes," both in the *American Economic Review*, vol. 89 (September 1999), pp. 947-958, and 959-973; Nicholas Souleles, "Consumer Response to the Reagan Tax Cuts," *Journal of Public Economics*, vol. 85, 2002, pp. 99-120). Studies that have not found effects, however, have generally excluded or under-represented low income individuals who are most likely to be liquidity constrained. In addition, the Souleles study may be flawed if overwithholding is used as a form of forced savings by low and moderate income individuals and the Parker study may be flawed if there are unmeasured seasonal differences in spending by wealth. In addition, in two studies examining individual responses to rebates (provided in 2001 and in 2008) evidence suggested that lower-income households spent more of their income. See David S. Johnson, Jonathan A. Parker, and Nicholas S. Souleles, "Household Expenditures and the Income Tax Rebate of 2001," *American Economic Review*, vol. 96, December 2006, pp. 1589-1610 and Jonathan Parker, Nicholas Souleles, David S. Johnson, and Robert McClelland, "Consumer Spending and the Economic Stimulus Payment of 2008," *American Economic Review*, vol. 103, no. 6, 2013, pp. 2530-2553. A study of the 2011 payroll tax cut using survey data that asked respondents about how they spent the tax cut found no differences between spending shares by income. See Grant Graziani, Wilbert van der Klaauw, and Basit Zadar, "Spending Response to the 2011 Payroll Tax Cuts," *American Economic Review*, vol. 8, no. 4, 2016, pp. 124-159. Parker and Souleles find, in their study of the 2008 rebate, that while answers to survey questions do not show a difference across incomes, inferences about actual spending do show a difference. See Jonathan A. Parker and Nicholas S. Souleles, "Reported Effects vs. Revealed Preference Estimates: Evidence from the Propensity to Spend Tax Rebates," *American Economic Review: Insights*, vol. 1, no. 3, pp. 273-290.

⁷ Congressional Budget Office, *Economic Stimulus: Evaluating Proposed Changes in Tax Policy, January 2002 and Options for Responding to Short-Term Economic Weakness*, January 2008.

⁸ See Nicholas Souleles, "The Response of Household Consumption to Income Tax Refunds," *American Economic Review*, vol. 89 (September 1999), pp. 947-958; and Nicholas Souleles, "Consumer Response to the Reagan Tax Cuts," forthcoming, *Journal of Public Economics*.

would not expect spending to rise when the refund is received, even though it might rise when an unplanned rebate is received. Thus, finding a smaller amount of spending out of a refund than out of tax cuts reflected in paychecks may not be very meaningful. Secondly, the model assumes that individuals were certain that the later phases of the Reagan tax cuts would be received. If there was some uncertainty, however, the fact that spending did not increase until the tax cut was actually received may partially reflect not the failure of the permanent income model, but the lack of certainty about receipt of the cut. If a differential does indeed exist, this effect could make the payroll tax cut (and sales tax holidays) more effective than a rebate. However, these “lump sum” effects would have to be offset by the distributional effects discussed in proposition I and supported by considerable empirical evidence. For that reason, it would be difficult to conclude that a payroll tax holiday would be more effective than a rebate directed at low income individuals. In addition, some evidence on the 2001 and 2008 tax rebates suggested that a large fraction of that rebate was spent.⁹ Evidence on the payroll tax cut in 2011 found a smaller share of that tax cut spent than the rebate, but that difference may reflect methodological and distributional differences or differences in economic conditions.¹⁰

Proposition 3. Certain types of temporary tax cuts may be more effective than permanent ones.

In general, the permanent income modeling of consumption, even when it does not hold in a pure form, suggests that temporary tax cuts will be less effective than permanent ones, presenting something of a dilemma because, tax cuts motivated for fiscal policy reasons need to be temporary (if they are not to hamper long term growth). However, temporary tax cuts that depend on spending (rather than receiving income) are likely to be more effective in the short run than permanent ones. During a period of slack employment, a payroll or individual income tax cut is simply a temporary windfall which can be spent at any time without any further consequence for the size of the tax cut. But if the tax benefit is triggered by spending, a temporary tax cut will be more effective (just as a temporary sale tends to induce a large response). The most common example is the investment tax credit or a similar subsidy, such as temporary partial expensing of investment, but the same would be true of a temporary sales

⁹ David Johnson, Jonathan Parker, and Nicholas S. Souleles, “Household Expenditures and the Income Tax Rebates of 2001,” *American Economic Review*, vol. 96, no. 5 (December 2006), pp. 1589-1610; Sumit Agarwal, Chunlin Liu, and Nicholas S. Souleles, “The Reaction of Consumer Spending and Debt to Tax Rebates: Evidence from Consumer Credit Data,” *Journal of Political Economy*, vol. 115, no. 6 (December 2007), pp. 986-1019; and Jonathan Parker, Nicholas Souleles, David S. Johnson, and Robert McClelland, “Consumer Spending and the Economic Stimulus Payment of 2008.” A recent survey of study of the 2009 income tax cut that would lead economists to predict a larger spending rate actually showed a smaller one on surveys. See Claudia R. Sahm, Matthew D. Shapiro, and Joel B. Slemrod, *Check in the Mail or More in the Paycheck: Does the Effectiveness of Fiscal Stimulus Depend on How it is Delivered?*, National Bureau of Economic Research Working paper 16246, July 2010, Joel B. Slemrod at <http://www-personal.umich.edu/~shapiro/papers/w16246.pdf>. This finding may simply reflect the lack of reliability of survey results, however. Parker, Souleles, Johnson and McClelland (cited above) found answers to survey questions to be poor predictors of response. In a subsequent study of the 2008 rebate, Parker and Souleles found survey responses related to statistical estimates of spending, but with higher responses from statistical evidence. They generally found a large fraction of the 2008 rebate to be spent with somewhat higher spending by lower-income households. See Jonathan A. Parker, Nicholas S. Souleles, “Reported Effects vs. Revealed Preference Estimates: Evidence from the Propensity to Spend Tax Rebates,” *American Economic Review: Insights*, vol. 1, no. 3, pp. 273-290.

¹⁰ Grant Graziani, Wilbert van der Klaauw, and Basit Zadar, “Spending Response to the 2011 Payroll Tax Cuts,” *American Economic Review*, vol. 8, no. 4, 2016, pp. 124-159. This study relied on survey data.

tax holiday. Although expensing of equipment is no longer an option (as 100% is currently allowed following the 2017 tax cut), investment credits would still be a possible investment incentive.

Note that while this feature may make a temporary tax cut more effective than a permanent one, it does not mean that the stimulus is more effective than other alternatives when all factors are considered. Most evidence suggests that investment subsidies have a small effect on investment and that the temporary investment subsidy enacted in 2006 was not very effective.¹¹ And, it may be particularly difficult to induce investment (even with a temporary subsidy) when excess capacity exists. While firms benefit from the temporary subsidy, they lose the benefit of delaying cash outlays. If investment is insensitive to these cost effects, a subsidy directed at increasing consumption may be more effective even if the latter is not the type where the temporary nature provides a benefit. In the case of the sales tax holiday versus other individual cuts, there may be a substantial implementation lag in arranging the sales tax holiday since sales taxes are imposed by the states, and fiscal stimulus may be applied at the wrong time. Moreover, the anticipation of the holiday should be contractionary. That is, a pre-announced future temporary spending subsidy is initially contractionary.

Proposition 4. Corporate tax cuts that do not make new investments more profitable would not have much effect; corporate rate cuts are less effective than investment subsidies.

One proposal considered in the past was a repeal of the corporate alternative minimum tax with a refund of existing credits. Such a change does not necessarily make new investment more profitable; indeed, it is possible that new investment may be subject to higher tax burdens under the regular rates than under the lower rates in the AMT. The corporate AMT was permanently repealed after the 2017 tax cut, but other measures of a similar nature might be considered. An extension of net operating loss (NOL) carrybacks was proposed in the 2009 stimulus package and would likely not make investments more profitable although a restoration of NOLs (which were eliminated in the 2017 tax cut, might be considered to aid businesses severely affected by COVID-19).¹²

Economic theory suggests that the investment decision should be driven by its expected profitability. A tax decrease not associated with that profitability should have no effect on investment. Rather, a tax decrease (which increases a firm's cash flow) is more likely to be spent on reducing debt, or paying out dividends. Both choices would not expand aggregate demand.¹³ Similarly, a corporate rate reduction, which largely benefits existing capital, would have modest effect compared to a stimulus directed at new investment. An extension of net

¹¹ See CRS Report RS22790, *Tax Cuts for Short-Run Economic Stimulus: Recent Experiences with Rebates and Bonus Depreciation*, coordinated by Jane G. Gravelle and CRS Report R43432, *Bonus Depreciation: Economic and Budgetary Issues*, by Jane G. Gravelle for a review of the evidence indicating that this investment incentive was not very effective. See also CRS Report R41034, *Business Investment and Employment Tax Incentives to Stimulate the Economy*, by Thomas L. Hungerford and Jane G. Gravelle (available upon request) for a broader comparison of business incentives.

¹² See CRS Insight IN11240, *COVID-19: Potential Role of Net Operating Loss (NOL) Carrybacks in Addressing the Economic Effects*, by Mark P. Keightley.

¹³ It is possible that knowledge of a tax cut could induce stockholder's consumption, or that cash flow translated into dividends would do so, but this effect is delayed and less certain than a direct tax benefit, as well as accruing to higher income individuals who are less likely to spend it.

operating loss carrybacks as proposed in the 2009 stimulus package would likely not make investments more profitable (although such a measure might be considered to aid businesses severely affected by COVID-19).

There is a potential constraint, however: if the firm does not have access to outside capital or finds outside capital excessively costly, cash flow might have an effect on investment. This effect would be likely, however, to be focused on small firms. There is some empirical evidence of a positive relationship between firm investment and cash flow. However, interpreting this evidence with respect to the effectiveness of a corporate cash flow as a stimulus to investment spending during an economic contraction is hampered by two important reservations. First, in most cases, cash flow is correlated with the productivity of investment and investment growth, and investment may be responding not to cash flow but to investment outlook. Secondly, even if there is some independent effect of cash flow in normal circumstances, then whether an increase in cash flow would induce a firm to make new investments during periods of excess capacity is doubtful.¹⁴ In any case, a choice that is more focused on investment (such as an investment subsidy) would have a more pronounced effect than one that is not. During the period of tight credit now being experienced a net operating loss carryback may have more effect because distressed firms are finding it more difficult to borrow.

General corporate rate cuts are less likely to be effective than investment subsidies because they have a smaller “bang-for-the-buck” because much of their cost is a windfall that only affects cash flow and not the return to new investment. Since even temporary investment subsidies do not appear to have worked effectively, a corporate rate cut or other provision that primarily affects cash flow would be expected to have a small effect.

Chapter 401

PAYROLL TAX CUTS AS AN ECONOMIC STIMULUS RESPONSE TO CORONAVIRUS DISEASE (COVID-19)*

Donald J. Marples and Molly F. Sherlock

The current coronavirus disease (COVID-19) outbreak has increased concerns that the U.S. economy could be affected as part of a global economic downturn. A range of fiscal and monetary policy tools have been used to address prior times of economic weakness. One option for fiscal stimulus is a temporary payroll tax cut for employees. This option was used to address economic weakness in 2011 and 2012. On March 2, 2020, President Trump and others expressed interest in a one-year payroll tax cut to help bolster the economy.

WHAT ARE PAYROLL TAXES?

Payroll taxes are collected to finance certain entitlement programs, including Social Security, parts of Medicare, and Unemployment Compensation (UC). Social Security's old age, survivors, and disability insurance (OASDI) payroll tax is paid by eligible workers and their employers, and it finances the Social Security trust funds. The tax equals 6.2% of wages on the taxable earnings base (\$137,700 in 2020). This tax is paid by both employers and employees (with self-employed individuals paying both the employer and the employee share, or 12.4%).

STIMULUS EFFECTS OF A TEMPORARY REDUCTION IN PAYROLL TAXES

Short-term fiscal stimulus measures aim to boost economic activity primarily through increases in the demand for goods and services. The Congressional Budget Office (CBO), in

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11230, dated March 5, 2020.

testimony before Congress, previously identified three key criteria commonly used to assess the stimulating effects of policy proposals: (1) timing, (2) cost-effectiveness, and (3) consistency with long-term fiscal objectives. The following sections evaluate a payroll tax rate reduction using these criteria.

Timing

To be effective, short-term stimulus should affect the economy while it is in a period of economic weakness. Although there is general agreement that the coronavirus will have dampening effects on the U.S. economy, there is substantial uncertainty regarding the magnitude of these effects. The Federal Reserve Federal Open Market Committee decision to lower the federal funds rate by half a percentage point is indicative of the risk the coronavirus poses to the economy. Many fundamentals of the U.S. economy, however, remain strong. Unemployment is at its lowest level since the 1960s, consumer spending is strong, and the economy remains in its longest period of economic expansion. Some Members of Congress and other commentators have expressed skepticism regarding fiscal stimulus in the form of a payroll tax cut as a coronavirus response. Others believe the situation warrants an immediate response that includes some form of fiscal stimulus. Relative to most other forms of fiscal stimulus, a payroll tax cut could be implemented relatively quickly. It could also be designed to expire as the economy strengthens.

Cost-Effectiveness

Effective short-term stimulus maximizes the increase in output and employment per dollar of budgetary cost. This is often colloquially referred to as the policy's "bang for the buck." Economists more often use the term *multiplier effect*. The multiplier effect of a fiscal policy depends on the fraction of additional income spent, as opposed to saved, on goods and services relative to the lost federal revenue. Provisions targeted at low-income individuals or the unemployed often are expected to be more cost-effective—have larger multiplier effects—than broad tax rate reductions, as those facing financial constraints are more likely to fully spend any additional disposable income.

Considering the source of the economic weakness can inform analysis of the likely effectiveness of a payroll tax cut. A payroll tax cut does not address supply-chain disruptions and might have limited effectiveness if the economy were positioned to snap back on its own after the shock—referred to as a "V-shaped" economic disruption. If, however, the coronavirus-induced economic slowdown leads to layoffs, reduced hours, or reduced consumer spending, a payroll tax cut could help offset reduced demand.

A 2015 CBO working paper presented data suggesting that multipliers vary according to the strength of the economy—with the smallest multipliers occurring when the economy is at or near full employment. A payroll tax cut enacted in a strong economy likely would have less "bang for the buck." Currently, the coronavirus does not appear to have caused widespread economic damage, and a statement from the G7 Finance Ministers and Central Bank Governors affirmed a readiness to respond if economic conditions deteriorate. As noted above, however, the situation is evolving.

Consistency with Long-Term Fiscal Objectives

Effective short-term stimulus should not hinder long-term fiscal sustainability. Any reduction in payroll taxes, by itself, adds to short-term budget deficits and could be at odds with the long-term goal of debt sustainability. This is a consideration given that the budget deficit and federal debt are higher than their historical averages, relative to the size of the economy.

To address long-term fiscal objectives, a temporary reduction in payroll taxes could include offsets to reduce or eliminate the net budgetary cost of the proposals. Offsets are, by definition, contractionary, as they either cut spending or raise taxes—though the timing of the offsets could be designed to apply their contractionary effects in later years.

In the past, the effect of payroll tax cuts on federal tax revenue has been substantial. The temporary payroll tax cut effective for 2011 reduced federal tax revenue by \$111.7 billion. The two-month extension for early 2012 reduced federal revenue by \$20.8 billion, and extending the payroll tax cut through the remainder of 2012 reduced federal revenue by \$93.2 billion. When payroll tax cuts were used as economic stimulus in 2011 and 2012, the Social Security trust fund was “made whole” by a transfer of general revenue.

Chapter 402

FEDERAL EXECUTIVE AGENCIES: HIRING FLEXIBILITIES FOR EMERGENCY SITUATIONS*

Barbara L. Schwemle

On January 31, 2020, Secretary of Health and Human Services Alex Azar declared a public health emergency for the United States in response to Coronavirus Disease 2019 (COVID-19). To assist the federal government in responding to the emergency, Congress passed legislation that provides Direct-Hire Authority (DHA) to the Department of Health and Human Services (HHS). The U.S. Office of Personnel Management (OPM) has also reiterated long-standing guidance on flexibilities for hiring in executive agencies that are codified in Title 5 of the *United States Code* and Title 5 of the *Code of Federal Regulations*.

DIRECT-HIRE AUTHORITY

Section 302 of P.L. 116-123 (H.R. 6074), the Coronavirus Preparedness and Response Supplemental Appropriations Act, 2020, as enacted on March 6, 2020, provides the HHS Secretary with DHA to appoint individuals to positions that perform critical work related to coronavirus. The law states that appointments may be made without regard to Title 5, Sections 3309-3319, of the *U.S. Code*, which prescribe veterans' preference requirements, requirements for rating and ranking applicants, and category rating procedures that increase the number of eligible candidates a selecting official may choose from. Still, public notice of positions the department seeks to fill would need to be given. And, the Secretary would need to determine that a public health threat exists.

Under Section 3304(a)(3), OPM may also authorize an agency to appoint candidates directly to positions without regard to Sections 3309-3318. The statute provides that public notice must be given for positions the agency seeks to fill. OPM would need to determine that there exists a severe shortage of candidates (for the Department of Veterans Affairs, there

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IF11468, dated March 19, 2020.

must be a severe shortage of highly qualified candidates) or that there is a critical hiring need. OPM regulations indicate that there is a severe shortage of candidates when “an agency is having difficulty identifying candidates possessing the competencies or the knowledge, skills, and abilities required to perform the job requirements despite extensive recruitment, extended announcement periods, and the use, as applicable, of hiring flexibilities such as recruitment or relocation incentives or special salary rates.” A critical hiring need occurs when “an agency has a need to fill the position(s) to meet mission requirements brought about by circumstances such as, but not limited to, a national emergency, threat, potential threat, environmental disaster, or unanticipated or unusual event or mission requirement, or to conform to the requirements of law, a Presidential directive or Administration initiative.”

The regulations also provide that OPM may decide independently that a severe shortage exists or that there is a critical hiring need or may make a decision about granting DHA in response to an agency’s written request. An agency with delegated examining authority may request DHA for a position or group of positions in the competitive service at pay grade GS-15 (or equivalent) and below. OPM determines the length of the authority. The regulations specify the evidence that must support an agency’s request. Periodically, OPM reviews DHAs and may extend them if the conditions justifying their use are continuing. DHAs may be terminated or modified when changes occur in the justifying conditions or when an agency does not use them properly. An agency must also report to OPM when there are adequate numbers of qualified candidates for positions filled by direct hire. (5 C.F.R. Part 337, Subpart B) OPM maintains a webpage with information on DHA, including templates for submitting direct-hire requests based on a severe shortage of candidates and critical hiring need.

GUIDANCE ON HIRING FLEXIBILITIES

On February 7, 2020, OPM issued guidance on human resources flexibilities for COVID-19 that included policies related to hiring. With regard to DHA authorities, OPM reminded agencies that direct hire is authorized government-wide for certain positions, including the following:

- Medical officers, nurses, diagnostic radiologic technicians, and pharmacists for all grade levels and locations;
- Information technology management (information security) for GS-9 and above at all locations;
- Veterinary medical officers for GS-11 through GS-15 nationwide, including overseas territories and commonwealths, indefinitely, until terminated;
- Scientific, technical, engineering and mathematics for GS-11 through GS-15 nationwide through October 10, 2023; and
- Cybersecurity-related positions for GS-12 through GS-15 nationwide, indefinitely, until terminated.

Individuals in the positions listed above may be appointed as competitive service career, career-conditional, term, or temporary employees. The guidance advised an agency to contact OPM “if it believes it has one or more occupations for which an agency-specific direct hire authority may be appropriate in support of relief and recovery efforts.”

Competitive service positions are civil service positions in the executive branch that are not specifically excepted from the competitive service by or under statute, positions to which appointments are made by nomination for confirmation by the Senate (unless the Senate otherwise directs), and positions in the Senior Executive Service (SES) (5 U.S.C. §2102(a)). Competitive service positions require applicants to compete against one another in open competition based on job-related criteria to obtain employment (5 C.F.R. Parts 212, 330, and 332).

Several long-standing hiring flexibilities available to federal agencies were identified by OPM in reiterating its guidance:

Excepted Service Appointment—Temporary Emergency Need (5 C.F.R. §213.3102(i)(3)). Agencies may appoint individuals for 30 days and may extend the appointment for up to an additional 30 days if continued employment is essential to the agency's operations. The same individual may not be employed for more than 60 days in a 12-month period. The agency determines the qualification requirements. The authority may be used to fill senior-level and lower-level positions. Excepted service positions are civil service positions that are not in the competitive service or the SES (5 U.S.C. §2103(a)). Qualification standards and requirements for these positions are established by the individual agencies. The Title 5 rules on appointment (except for veterans' preference), pay, and classification do not apply (5 C.F.R. Parts 213 and 302).

SES—Limited Appointments (5 C.F.R. Part 317, Subpart F). Agencies may appoint career employees to limited term or limited emergency appointments provided such appointments are within the space allocations limit previously authorized by OPM. If an appointment would not be within that limit, an agency may request a temporary space allocation. Agencies may request authority from OPM to appoint non-career employees to limited term or limited emergency appointments. A limited term appointee is an individual appointed under a nonrenewable appointment for a term of three years or less to an SES position the duties of which will expire at the end of such term. A limited emergency appointee is an individual appointed under a nonrenewable appointment, not to exceed 18 months, to an SES position established to meet a bona fide, unanticipated, urgent need (5 U.S.C. §3132(a)(5)(6)).

SES positions are classified above GS-15 or in level IV or V of the Executive Schedule, or an equivalent position, and are not filled by presidential appointment with the advice and consent of the Senate. SES members, among other duties, direct the work of an organizational unit and exercise important policymaking, policy-determining, or other executive functions (5 U.S.C. §3132(a)(2)) service firms to quickly provide specific services (but not for SES, managerial, or supervisory positions). A contract may be extended for an additional 120 workdays.

Individuals provided by temporary help service firms are not considered or treated as federal employees for any purpose.

Competitive Service Appointment—Temporary Appointments, 120 Days or Less (5 C.F.R. §330.609(c) and 5 C.F.R. §330.707(e)). Agencies may make appointments of 120 days or less without first selecting a surplus or displaced employee who is eligible for appointment under an Agency Career Transition Assistance Plan (CTAP) or an Interagency Career Transition Assistance Plan (ICTAP).

For appointments of longer duration, the CTAP and the ICTAP may be used to identify well-qualified displaced federal employees who are available for immediate employment (5 C.F.R. Part 330, Subparts F and G).

Reemployment Priority List (RPL) (5 C.F.R. Part 330, Subpart B). The RPL is used by agencies to give reemployment consideration to their current and former competitive service employees who will be, or were, separated by reduction in force or who are fully recovered from a compensable injury after more than one year (5C.F.R. §330.201). Agencies may use the RPL as a source of qualified individuals who are available for temporary appointments (generally, one year with up to one additional year), term appointments (more than one year but not more than four years), or permanent appointments in the competitive service. An agency may apply an exception to choosing someone from the RPL from the list of exceptions at Title 5, Section 330.211, of the *Code of Federal Regulations*.

Reemployed Annuitants [5 U.S.C. §8344(i), §8468(i)]. Agencies, without OPM approval, may reemploy retirees without applying the dual compensation salary offset, which prohibits federal retirees from getting the full combined value of their salary and annuity upon reemployment. Appointments are for one year or less.

Reemployed annuitants may work 520 hours during the first six months of retirement, 1,040 hours during any 12-month period, and 3,120 total hours during any period.

Authorization for a longer time period requires OPM approval. Reemployment may not exceed 2.5% of the full- time workforce at any time. An agency must explain and justify the reemployment if it exceeds 1% of the full-time workforce.

Reemploying Recipients of Voluntary Separation Incentives (commonly referred to as buyouts) (5 U.S.C. §5597 note). Upon agency request, OPM may authorize agencies to rehire federal employees who retired or separated with buyouts. Laws authorizing buyouts may have included a requirement that the buyout be repaid upon government reemployment. Agencies may request that OPM grant a waiver of any buyout repayment.

Chapter 403

SBA ECONOMIC INJURY DISASTER LOANS FOR COVID-19*

Bruce R. Lindsay

The current COVID-19 pandemic may have significant economic implications for businesses and nonprofit organizations, including negative impacts on imports, global supply chains, and tourism. Furthermore, if COVID-19 becomes increasingly widespread or prolonged it may slow global growth, and some businesses may be forced to furlough or lay off workers. One potential form of assistance to small businesses is Small Business Administration (SBA) economic injury disaster loans (EIDLs).

EIDL OVERVIEW

EIDLs provide eligible small businesses and nonprofit organizations up to \$2 million to help meet financial obligations and operating expenses that could have been met had the disaster not occurred. Loan proceeds can only be used for working capital necessary to enable the business or organization to alleviate the specific economic injury and resume normal operations. Interest rates for EIDLs are statutorily set at 4% per annum or less and can have maturities up to 30 years. Collateral is generally required for loans over \$25,000 if it is available, though SBA will not decline loans for a lack of collateral.

EIDLs are available only to businesses and private and nonprofit organizations that are located in a declared disaster area, have suffered substantial economic injury, are unable to obtain credit elsewhere, and are defined as small by SBA size regulations. Small businesses in declared counties (and contiguous counties) apply directly to the SBA for EIDLs.

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11232, updated March 18, 2020.

SBA DECLARATION ACTIVITY

On March 6, 2020, Congress signed into law P.L. 116-123. In addition to providing supplemental funding to several agencies, the act deemed the coronavirus disease (COVID-19) outbreak a declarable disaster under the Small Business Act. The amendment allows the Small Business Administrator to issue disaster declarations that make SBA EIDLs available to eligible small businesses.

On March 16, 2020, the SBA Administrator began issuing declarations for SBA EIDLs in response to states seeking SBA disaster assistance for small businesses. SBA EIDL declarations are not automatic, they must be requested by a state governor. Historically, to be eligible SBA has required a state or territory to “provide documentation certifying that at least five small businesses have suffered substantial economic injury as a result of the disaster, with at least one business located in each declared county/parish.” Under new criteria issued by the SBA, states/territories now “are only required to certify that at least five small businesses within the state/territory have suffered substantial economic injury, regardless of where the businesses are located.”

ADDITIONAL DECLARATIONS THAT TRIGGER SBA EIDLs

EIDLs may also be made available pursuant to a disaster declaration authorized by the SBA, based on a notification from the Secretary of Agriculture or the Secretary of Commerce, if a governor certifies that eligible small businesses have suffered substantial economic injury as a result of commercial fishery failures or fishery resource disasters.

The third type of declaration authorizing EIDLs is a major disaster declaration issued by the President under the Robert T. Stafford Disaster Relief and Emergency Assistance Act that authorizes both Individual Assistance (IA) and Public Assistance (PA). There is some debate whether an infectious disease outbreak could be considered a major disaster given that the list of incidents that explicitly qualify as a major disaster under the Stafford Act does not include outbreaks of infectious diseases. In the past some incidents were considered ineligible due to definitional reasons (such as the major disaster denial for the Flint water contamination incident). Moreover, the thresholds used to determine whether to provide IA and PA are based on damages to homes and public infrastructure. It is unclear how COVID-19 damages would be evaluated to determine whether a state warranted a major disaster declaration. The President, however, has stated that COVID-19 is of “such severity and magnitude nationwide that requests for a declaration of a major disaster ... may be appropriate” if requested by a state governor or tribal chief (tribal nations under the Stafford are entitled to the same types of assistance as a state).

It is important to note that the COVID19 emergency declarations issued on March 13, 2020, by the President, including the emergency declared under the Stafford Act, did not trigger SBA EIDLs.

Chapter 404

COVID-19 AND THE CRUISE SHIP INDUSTRY*

John Frittelli

The cruise ship industry has been heavily impacted by coronavirus disease 2019 (COVID-19). Major cruise lines have canceled trips from U.S. ports over the next month. In recent weeks, several cruise ships have been quarantined offshore and U.S. government health officials have advised against cruise ship travel for the time being. These events have raised questions about government oversight over the cruise industry, the potential economic harm the coronavirus could have on the industry, and whether the industry is largely America- or foreign-based.

EMPLOYMENT IN THE CRUISE SHIP INDUSTRY

While most of the major cruise lines are incorporated or otherwise domiciled in foreign countries, they have headquarters in the United States, with office staff who handle advertising, sales, bookings, and vessel planning. According to federal government data, Miami has the largest contingent of workers employed by the cruise industry (North American Industry Classification System code 483112), with Los Angeles and Washington State as secondary centers of employment. In terms of number of cruise ship port calls in 2018, Florida was the leading state with over 3,000 port calls, followed by Alaska with nearly 2,000, and California with over 500. Puerto Rico also had over 500 cruise ship port calls, and the U.S. Virgin Islands nearly 500. Ship chandlers are another significant employer in port areas, as they supply navigation-related parts and equipment as well as food, beverages, linens, and other passenger-related supplies.

Although U.S. nationals are employed in the “onshore” business segment of the cruise industry, in the offshore segment (aboard ships), foreign workers fill most positions. Almost all oceangoing cruise ships calling at U.S. ports are “foreign-flagged,” meaning they are registered in foreign countries, and particularly in “open-registry” countries such as Panama,

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11245, dated March 16, 2020.

Bermuda, Malta, the Bahamas, and the Marshall Islands. While U.S. law requires that passengers being transported from one U.S. point to another U.S. point be carried in only U.S.-built, -owned, and -crewed vessels, this law does not apply to cruise ship voyages that include foreign port calls or that embark and disembark passengers at the same dock. Plus, Puerto Rico and the U.S. Virgin Islands are exempt from this law. Open registries allow cruise ships to crew and staff their vessels with citizens other than from the registering country, and these registries generally assess lower fees and taxes. The Philippines is a popular home country for many ship crews, particularly sailors, engine room mechanics, and hotel and food service workers. U.S. nationals are more likely to be hired as entertainers on ships catering to American passengers. A cruise ship with thousands of passengers can have a staff and crew of several hundred or more on board.

FEDERAL OVERSIGHT OF CRUISE SHIPS

Three federal agencies have the most direct interaction with cruise ships when they call at a U.S. port: the Coast Guard, Customs and Border Protection (CBP), and the Centers for Disease Control and Prevention (CDC). The Coast Guard's authority is largely in the areas of safety, security, and pollution prevention with respect to the ships and their harbor transits. CBP's authority comes into play mostly once a ship is docked, and is centered around screening the arriving passengers. The CDC focuses on the sanitary condition of the ship.

Ships must report to the Coast Guard four days prior to arriving at a U.S. harbor. The Coast Guard can board and inspect a ship before entering the harbor, but usually inspections and boarding take place at the dock. Ship anchorage areas are designated in or outside harbors for ships ordered into quarantine (42U.S.C. 267, 33 C.F.R. §109.05(b)). For security reasons, the Coast Guard may escort a cruise ship in and out of a harbor, typically with a patrol boat (or boats). The Coast Guard "Captain of the Port" is the most senior Coast Guard official in a local port area, and has considerable discretion in making decisions related to the safety and security of harbor operations.

The Coast Guard inspects cruise ships for compliance with international safety, security, and pollution prevention standards established by the United Nations' International Maritime Organization (IMO), as well as those laws specific to the United States. Relevant IMO standards for safety and security include the Safety of Life at Sea (SOLAS) convention, the Standards of Training, Certification, and Watchkeeping for Seafarers (SCTW), and the International Ship and Port Facility Security (ISPS) Code. While the SCTW includes minimal requirements for medical-related training for some of the crew, the convention mostly concerns the training and qualifications of the navigation crew.

U.S.-specific law includes the Cruise Vessel Security and Safety Act of 2010 (P.L. 111-207). In response to concern over sexual assaults on cruise ships, this law requires cruise ships to have medical staff on board, to include either a physician or registered nurse, to attend to a victim of sexual assault (46 U.S.C. §3507(d)(3)(A)). The Coast Guard checks the qualifications of the medical staff during its boarding examinations. The cruise industry has issued medical staffing guidance that exceeds current U.S. law. Bills introduced in the 116th Congress would expand the medical staffing requirements for cruise ships (H.R. 5096, S. 3124).

Ships entering and departing U.S. ports must report to CBP before doing so. CBP screens cruise ship passengers essentially in the same manner that it does for arriving international air travelers.

CDC conducts sanitary inspections of cruise ships seeking to prevent gastrointestinal and other illnesses pursuant to the Public Health Service Act (42 U.S.C. §269). This inspection program began in the early 1970s. Cruise ships are subject to two unannounced CDC inspections per year. Cruise ships must report to CDC any sicknesses or deaths of crew or passengers that have occurred in the 15 days prior to a U.S. port arrival (42 C.F.R. §71.21). In their annual reports, cruise lines typically note disease outbreaks and concerns for the risk of illness as a risk factor for potential investors.

Chapter 405

THE FINANCIAL INDUSTRY AND CONSUMERS STRUGGLING TO PAY BILLS DURING THE COVID-19 (CORONAVIRUS) OUTBREAK*

Cheryl R. Cooper

A growing number of cases of Coronavirus Disease 2019 (COVID-19) have been identified in the United States, significantly impacting many communities. For background on the coronavirus, see CRS In Focus IF11421, *COVID-19: Global Implications and Responses*, by Sara M. Tharakan et al.

This outbreak may continue to cause disruptions as federal, state, and local governments limit public gatherings, close schools, and encourage workers to telework to contain the coronavirus's spread. While this situation is evolving rapidly, the economic impact may be large due to illnesses, quarantines, and other business disruptions.

Consequently, many Americans may lose income and face financial hardship due to the coronavirus outbreak. Some workers may need to take time off work if they or their families fall ill. In addition, layoffs or reduced hours may impact workers in particular industries affected by the outbreak, such as the travel, restaurant, and entertainment industries. To address these concerns, on Saturday, March 14, the House passed H.R. 6201, which, among other things, expands sick leave access, unemployment insurance, and food assistance benefits. Even if this bill is enacted, some families may continue to feel the economic impact. This Insight focuses on possible policy options relating to the financial services industry for consumers who may have trouble paying their bills due to the outbreak.

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11244, dated March 16, 2020.

PAYMENT RELIEF FOR CONSUMER LOANS

On Monday, March 9, federal and state financial regulators coordinated a statement to the financial industry, encouraging it to help meet the needs of consumers impacted by the coronavirus outbreak. They stated that “financial institutions should work constructively with borrowers and other consumers in affected communities,” and that “prudent efforts that are consistent with safe and sound lending practices” would not be criticized by regulators. This statement was similar to past statements by financial regulators during events such as natural disasters and government shutdowns. On Friday, March 13, the Office of the Comptroller of the Currency (OCC) and the Federal Deposit Insurance Corporation (FDIC) expanded on this statement with more detailed guidance for the institutions they regulate.

In addition, on Wednesday, March 11, the chairwoman and other members of the House Financial Services Committee sent a letter to financial services organizations “[urging them] to proactively help [their] customers who may be experiencing temporary financial hardship in making payments on their existing credit obligations as a result of this crisis.”

During past responses to natural disasters, government shutdowns, or other similar events, the financial industry has provided financial assistance to some impacted consumers. For example, they sometimes help consumers having trouble paying their mortgages, credit cards, or other loans due to temporary financial problems through forbearance plans, which are agreements that allow extended time for consumers to become current on their payments. Financial institutions also may agree to limit late or other fees and extend credit to ease consumer financial struggles amid the outbreak. However, some of these efforts may be more difficult for some institutions if they require changes in credit contracts.

Financial regulatory agencies might also consider employing other policy tools to encourage banks to provide this type of financial assistance. For example, bank regulators may award Community Reinvestment Act (CRA) credits after major disasters in adversely affected communities, even those where the bank does not primarily collect deposits. Regulator guidance under the CRA encourages banks during major disasters to meet customer cash and financial needs by waiving fees and penalties, deferring or skipping loan payments, or other related activities. In order to qualify, the federal government, through the Federal Emergency Management Agency (FEMA), must declare a “designated disaster area” (Category A or B). FEMA’s national emergency declaration on Friday, March 13, does not trigger this statute.

Although the coronavirus outbreak may be similar to these other events, making it consistent for the financial industry to provide assistance, it is also possible that this current outbreak may be more widespread than past events. Therefore, it might be more challenging for institutions to provide support alone. Some banks have recently announced measures they are taking to help assist impacted consumers. However, it remains unclear whether these efforts will be sufficient, particularly depending on how large the financial consequences of the outbreak become in the United States. For example, in Italy, which is currently one of the hardest hit countries in the world, mortgage payments generally have been suspended to help people during the crisis. However, this type of action may require direct government support to the financial industry, and other types of government policies outside of the financial industry might better target impacted Americans and be more appropriate given the economic situation.

OTHER POTENTIAL RESPONSES TO HELP CONSUMERS

Other policy options may be available to help consumers having trouble paying their bills during the coronavirus outbreak. For example, consumers can harm their credit scores when they miss consumer loan payments, which can impact their access to credit in the future. In this way, the credit reporting industry may be in a position to help affected consumers. During natural disasters, lenders have the ability to flag affected borrowers by using special comment codes when reporting to credit bureaus. A similar approach might be appropriate during the coronavirus outbreak. Encouraging lenders to furnish this information to credit bureaus could allow the credit reporting industry to limit the impact on affected consumers' credit scores and their future access to credit. Moreover, legislation could be considered to help prevent declining credit scores. However, it may be difficult to target this type of policy to the most impacted people, and, if the policy is too widespread, it may potentially harm the predictiveness of credit scores in the future.

Communication and financial education may also play an important role. Many consumers having trouble paying their bills may not realize that their financial institutions can provide loan forbearance, access to credit, or other assistance under extenuating circumstances. Financial institutions and government agencies such as the Bureau of Consumer Financial Protection (CFPB) may be able to conduct outreach to consumers to let them know about their possible options.

Chapter 406

FEDERAL RESERVE: RECENT ACTIONS IN RESPONSE TO COVID-19*

Marc Labonte

Coronavirus (COVID-19) has created significant economic disruption. In response, the Federal Reserve (Fed) has taken a number of steps to promote economic and financial stability involving the Fed's monetary policy and "lender of last resort" roles. Some of these actions are intended to stimulate economic activity by reducing interest rates and others are intended to provide liquidity to financial markets so that firms have access to needed funding.

ACTIONS TO LOWER INTEREST RATES

Federal Funds Rate

Traditionally, the Fed conducts monetary policy by changing the federal funds rate, the overnight interbank lending rate. In response to COVID-19, on March 3, the Fed reduced the federal funds rate from a range of 1.5%-1.75% to a range of 1%-1.25% to stimulate economic activity. On March 15, it reduced the range to 0%-0.25%. Economists refer to this as the "zero lower bound" to signify that the Fed's traditional monetary policy tool has been exhausted at this point, and cannot be used to provide additional stimulus. This is the second time this interest rate has ever hit the zero lower bound—the first time was in 2008, during the financial crisis.

At that time, the Fed developed two other tools to provide stimulus at the zero lower bound—forward guidance and quantitative easing. Both aim to reduce long-term interest rates which, unlike short-term rates, are not directly determined by the Fed, but are important for stimulating economic activity. These tools are being revived in response to COVID-19.

* This is an edited, reformatted and augmented version of a Congressional Research Service publication IN11259, prepared for Members and Committees of Congress dated March 20, 2020.

Forward Guidance

Forward guidance refers to Fed public communications on its future plans for short-term interest rates, and it took many forms following the 2008 financial crisis. As monetary policy returned to normal in recent years, forward guidance was phased out. It is being used again today. For example, when the Fed reduced short-term rates to zero on March 15, it announced that it “expects to maintain this target range until it is confident that the economy has weathered recent events and is on track to achieve its maximum employment and price stability goals.”

Quantitative Easing

Large-scale asset purchases, popularly referred to as *quantitative easing* or *QE*, were also used during the financial crisis. Under QE, the Fed expanded its balance sheet by purchasing Treasury securities and government-backed mortgage-related securities. Three rounds of QE from 2009 to 2014 increased the Fed’s securities holdings by \$3.7 trillion.

On March 15, the Fed announced that it would increase its Treasury securities holdings by at least \$500 billion and its mortgage-backed securities holdings by at least \$200 billion “over the coming months.” As a result, the value of the Fed’s balance sheet is projected to exceed its post-financial crisis peak of \$4.5 trillion. One notable difference from previous rounds of QE is that the Fed is purchasing securities of different maturities, so the effect likely will not be concentrated on long-term rates.

ACTIONS TO PROVIDE LIQUIDITY

Reserve Requirements

On March 15, the Fed announced that it was reducing reserve requirements—the amount of vault cash or deposits at the Fed that banks must hold against deposits—to zero for the first time ever. As the Fed noted in its announcement, because bank reserves are currently so abundant, reserve requirements “do not play a significant role” in monetary policy.

Term Repos

The Fed can temporarily provide liquidity to financial markets by lending cash through repurchase agreements (repos) with primary dealers (i.e., large government securities dealers who are market makers). Before the financial crisis, this was the Fed’s routine method for targeting the federal funds rate. Following the financial crisis, the Fed’s large balance sheet meant that repos were no longer needed, until they were revived in September 2019. On March 12, the Fed announced it would offer a three-month repo of \$500 billion and a one-month repo of \$500 billion on a weekly basis through the end of the month in addition to the

shorter-term repos it had already been offering. These repos would be larger and longer than those offered since September.

Discount Window

In its March 15 announcement, the Fed encouraged banks (insured depository institutions) to borrow from the Fed's discount window to meet their liquidity needs. This is the Fed's traditional tool in its "lender of last resort" function. The Fed also encouraged banks to use intraday credit available through the Fed's payment systems as a source of liquidity.

Foreign Central Bank Swap Lines

Both domestic and foreign commercial banks rely on short-term borrowing markets to access U.S. dollars needed to fund their operations and meet their cash flow needs. But in an environment of strained liquidity, only banks operating in the United States can access the discount window. Therefore, the Fed has standing "swap lines" with major foreign central banks to provide central banks with U.S. dollar funding that they can in turn lend to private banks in their jurisdictions. On March 15, the Fed reduced the cost of using those swap lines and on March 19 it extended swap lines to nine more central banks.

Emergency Credit Facilities for Nonbanks

In 2008, the Fed created a series of emergency credit facilities to support liquidity in the nonbank financial system. This extended the Fed's traditional role as lender of last resort from the banking system to the overall financial system for the first time since the Great Depression. To create these facilities, the Fed relied on its emergency lending authority (Section 13(3) of the Federal Reserve Act). To date, the Fed has resurrected three of those facilities in response to COVID-19.

- The commercial paper market is another important source of short-term credit for financial and nonfinancial companies. On March 17, the Fed revived the commercial paper funding facility (CPFF) to purchase commercial paper, offsetting a drop in private demand.
- Like banks, primary dealers are heavily reliant on short-term lending markets in their role as securities market makers. Unlike banks, they cannot access the discount window. On March 17, the Fed revived the primary dealer credit facility (PDCF), which is akin to a discount window for primary dealers. Like the discount window, it provides short-term, fully collateralized loans to primary dealers.
- On March 19, the Fed created the Money Market Mutual Fund Liquidity Facility (MMLF), similar to a facility created during the 2008 financial crisis. The MMLF makes loans to financial institutions to purchase assets that money market funds are selling to meet redemptions.

Although there were no losses from these facilities during the financial crisis, assets of the Treasury's Exchange Stabilization Fund have been pledged to backstop any losses on the CPFF and MMLF today.

Chapter 407

COVID-19 AND STIMULUS PAYMENTS TO INDIVIDUALS: CONSIDERATIONS ON USING ADVANCED REFUNDABLE CREDITS AS ECONOMIC STIMULUS*

Margot L. Crandall-Hollick

In response to concerns about an economic slowdown stemming from the COVID-19 pandemic, policymakers have been considering a broad array of policy options. Some are targeted directly toward the individuals and industries that may be most affected. Others would more broadly seek to stimulate the economy. Among this latter category of policies, some have suggested a payroll tax cut, while others have proposed direct cash payments—“recovery rebates”—to virtually all households. One mechanism to provide cash payments relatively quickly is to create a new refundable tax credit and then advance it to households before they would otherwise claim it on their income tax returns. A similar policy was enacted most recently in 2008. This Insight addresses some common questions about advanced refundable tax credits.

WHAT IS A REFUNDABLE TAX CREDIT?

Tax credits reduce income taxes owed dollar for dollar; each dollar in tax credit is a one-dollar subtraction from income tax liability. Nonrefundable credits are limited by the taxpayer’s income tax liability, while refundable credits are not. Hence, taxpayers with little to no income tax liability—including many low-income taxpayers—can benefit from refundable tax credits. Refundable tax credits targeted toward low-income individuals and families are estimated to have relatively large stimulative effects compared to other policies—

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11247, dated March 17, 2020.

a large “bang for the buck”—because low-income populations tend to spend these amounts quickly. Some economists were concerned that the 2008 credit would not be effective because a lump-sum payment might be saved rather than spent. Empirical evidence based on studying a prior rebate found, however, that the rebate was largely spent.

Current refundable tax credits—the earned income tax credit (EITC) and the refundable portion of the child credit—benefit low-income families that include workers and children. These tax credits are received once a year when federal income tax returns are filed. Tax credit amounts are primarily based on the taxpayer’s earned income and number of qualifying children in the prior year (e.g., an EITC received in 2020 when 2019 tax returns are filed is based on 2019 income and family composition).

WHAT DOES “ADVANCING” A TAX CREDIT MEAN?

Advancing a tax credit effectively means issuing a tax credit for a given year before the tax return for that year has been filed (and before income taxes for that year have been calculated). The 2008 recovery rebates for individuals included in P.L. 110-185 were refundable tax credits against 2008 income taxes.

However, taxpayers did not need to wait to file their 2008 income tax returns in early 2009 to receive these credits. Instead, the law allowed the IRS to advance these credits in 2008, basing the advanced amount on income and family structure information from tax returns filed for the 2007 tax year. The credit equaled up to \$600 per person (\$1,200 for joint filers), with an additional \$300 per dependent child. Lower-income taxpayers tended to receive a smaller credit, while the credit phased out for taxpayers with incomes over \$75,000 (\$150,000 for married joint filers).

Advancing tax credits based on prior data can pose challenges if any of the parameters used to calculate the credit—like income and number of children—change from these prior values. For example, if a taxpayer’s 2019 income is significantly greater than their income at the end of 2020, an advanced credit estimated based on 2019 income may be larger than what a taxpayer is ultimately eligible for in 2020. (Even if an advanced payment is a fixed amount per person [does not vary by income], the final amount can still vary if family structure changes during the year.) This could result in taxpayers having to pay back the excess credit when they file their 2020 income tax returns (in early 2021). Insofar as this is a concern, policymakers can limit how much taxpayers have to pay back (for example, as is done with the advanced premium assistance tax credit), or they can bar repayments of excess advanced payments entirely, as was done with the 2008 recovery rebates.

HOW LONG WOULD IT TAKE FOR THE IRS TO BEGIN ISSUING ADVANCED CREDITS?

Past experiences with the IRS issuing advanced refundable tax credits may provide some guide on how long these policies take to implement. On January 28, 2008, H.R. 5140, which included the 2008 recovery rebates for individuals, was introduced in the House. Two weeks

later, on February 13, 2008, it was enacted as P.L. 110-185. Sixty-two days later, the IRS began issuing the first one-time rebate checks.

More than 120 million taxpayers received their payments by mid-July 2008. Taxpayers who had filed their 2007 tax returns and received a refund via direct deposit also received the 2008 recovery rebates via direct deposit. Otherwise, paper checks were mailed out to taxpayers using address information from 2007 income tax returns. A 2007 tax return had to be filed to receive a recovery rebate check. Those who did not receive a recovery rebate check could claim the benefit when filing a 2008 income tax return.

HOW MANY INDIVIDUALS COULD RECEIVE AN ADVANCED REFUNDABLE TAX CREDIT?

One concern that some have about using the federal tax system to administer direct cash payments to households is that not all individuals in the United States file income tax returns—either because their income is below the filing threshold or because they are not complying with federal tax laws. A 2017 CBO analysis estimated that of 292.6 million individuals who could be included on a federal income tax return (as the taxpayer, spouse, or dependent), 251.9 million were actually included—or 86%. The study estimated that the greatest share of nonfilers were lower-income individuals, especially those 65 years or older. As was noted above, the 2008 recovery rebate could be claimed by taxpayers who did not file a 2007 tax return. These nonfilers—which included many low-income individuals and seniors—could claim the credit on their 2008 returns when they filed them in 2009. The federal income tax system is limited in its ability to provide cash assistance to individuals quickly, particularly when those individuals are nonfilers.

Chapter 408

COVID-19 AND STIMULUS PAYMENTS TO INDIVIDUALS: SUMMARY OF THE 2020 RECOVERY REBATES IN THE CARES ACT (S. 3548)*

Margot L. Crandall-Hollick

ABSTRACT

The Coronavirus Aid, Relief, and Economic Security (CARES) Act (S. 3548) proposes direct payments of up to \$1,200 per person (\$2,400 for married taxpayers filing a joint tax return) and \$500 per child—“2020 recovery rebates.” Similar to the 2008 recovery rebates, these payments are structured as tax credits advanced to households that file an income tax return. Taxpayers that filed a 2018 income tax return would have this credit advanced to them in 2020, generally in the form of a direct deposit or check by mail. Thus, these taxpayers do not need to wait until 2020 tax returns are filed in 2021 to claim the credit. If they did not file a 2018 return, information from a 2019 return can be used for the advanced credit.

These payments are intended to broadly stimulate the economy in response to concerns about an economic slowdown stemming from the COVID-19 pandemic.

This Insight provides a brief overview of the proposed 2020 recovery rebates, with several simplified examples to illustrate payment amounts for different families.

CALCULATING THE CREDIT AMOUNT

The credit equals the *greater* of

1. the taxpayer’s *net income tax liability* up to \$1,200 (\$2,400 for married joint filers). Net income tax liability is the taxpayer’s income tax liability *before* the child tax credit and refundable tax credits (like the EITC); or

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. IN11262, dated March 20, 2020.

2. \$600 (\$1,200 for married joint filers) if the taxpayer has *qualifying income*. For the purposes of the basic credit, qualifying income is either
 - a. at least \$2,500 of earned income, social security income, or veterans' benefits; or
 - b. gross income above the standard deduction and \$1 of net income tax liability.

All eligible taxpayers would receive the minimum basic credit of \$600 (\$1,200 married joint filers).

Taxpayers eligible for the credit can receive an additional \$500 for each child that qualifies for the child tax credit.

The total credit phases out at a rate of 5% of adjusted gross income (AGI) above \$75,000 (\$150,000 for married joint returns).

As with any tax refund, these payments would not count as income or resources in determining eligibility for, or the amount of, any federally funded public benefit program.

Lower-income taxpayers with little or no income tax liability would tend to receive a smaller credit, on average. Tax credit amounts rise for higher-income taxpayers, until the tax credit phases out at the upper end of the distribution. The distribution of the 2020 recovery rebates may be similar to that of the 2008 recovery rebates.

OTHER FEATURES OF THE PROPOSED 2020 RECOVERY REBATES

- **SSN requirement:** Taxpayers must provide social security numbers (SSNs) for themselves, their spouse (if married filing jointly), and any child for whom they claim the \$500 child credit. Adoption taxpayer ID numbers (ATINs) are also acceptable for adopted children. Taxpayers who provide an individual taxpayer identification number (ITIN) are ineligible for the credit. Hence, married couples in which one spouse has an SSN and another has an ITIN are ineligible for the credit.
- **Nonresident aliens:** The credit is not available to nonresident aliens.
- **Territories:** The law includes a provision requiring the U.S. Treasury to make payments to territories (mirror code and non-mirror code) equal to the aggregate amount of credits claimed by their residents.
- **Past-Due debts:** The credit cannot be reduced for certain unpaid debts, including debts owed to a federal agency (excluding child support), past-due state income taxes, and unemployment compensation debts.
- **Appropriations:** The bill appropriates \$396.45 million in FY2020 for the administration of these payments.

ADVANCING THE PROPOSED 2020 RECOVERY REBATES

The bill would advance the credit, which would be received as a direct deposit or a check by mail. Without this advancing provision, taxpayers would have to wait until they file their 2020 income tax returns in early 2021 to claim this credit.

The advanced credit amount is estimated using the same formula as the 2020 recovery rebates, but based on taxpayers' 2018 income tax return information (if the taxpayer did not file a 2018 income tax return, 2019 income tax return information could be used instead).

If, when taxpayers file their 2020 income tax returns in 2021, they find that the advanced credit is greater than the actual credit, they *would not* be required to repay the excess credit. In contrast, if the advanced credit is less than the actual credit, the taxpayer would be able to claim the difference on their 2020 income tax return.

SIMPLIFIED EXAMPLES OF 2020 REBATE AMOUNTS

The following examples illustrate the rebate amount received in 2020 using the taxpayer's 2018 tax return. These are simplified examples and assume the taxpayer files a 2018 return, meets all the eligibility criteria of the credit, and only claims the standard deduction and child credit and EITC (if eligible).

Income tax liabilities are estimated using TAXSIM.

Low-Income Disabled Individual with Only Supplemental Security Income (SSI)

In general, cash public assistance for low-income populations, such as SSI, is not considered gross income and is excludable from gross income under a limited general welfare exclusion. In addition—excluding social security retirement benefits (§ 86(d)) and veterans' benefits—cash public assistance for low-income populations would not be considered qualifying income as defined in this bill. So if SSI is the individual's only source of income, they would be ineligible for the rebate.

Low-Income Single Worker with \$10,000 of Earned Income

This individual has \$0 of net income tax liability prior to applying the EITC (actual liability after the EITC is -\$403). Because they have qualifying income (earned income above \$2,500), they would receive a \$600 rebate.

Low-Income Senior with \$15,000 of Social Security Income

This individual has \$0 net income tax liability (and \$0 in actual liability). Because they have qualifying income (social security benefits above \$2,500) they would receive a \$600 rebate.

Married Couple with Two Children and \$50,000 of Earned Income

The couple has \$2,739 in net income tax liability prior to applying the child credit and EITC (actual liability after these credits is \$1,575). They would receive a \$3,400 rebate (\$2,400 basic credit and \$500 for each child).

Married Couple with Two Children and \$200,000 of Earned Income

The couple has \$30,819 in net income tax liability prior to applying the child credit (actual liability after this credit is \$26,819). Before applying the phaseout, the rebate would be \$3,400. As a result of the phaseout, they would receive a rebate of \$900.

Chapter 409

COVID-19 AND STIMULUS PAYMENTS TO INDIVIDUALS: HOW THE 2009 ECONOMIC RECOVERY PAYMENT WORKED*

William R. Morton

In response to concerns about an economic slowdown due to the Coronavirus Disease 2019 (COVID-19) outbreak, some lawmakers have expressed interest in providing direct cash payments to Americans. One option to provide such payments would be to establish a new advanced refundable tax credit, as was done in 2008 with “recovery rebates.” Although this option would disburse payments to the vast majority of Americans relatively quickly, it would not directly help those who do not file a federal income tax return. A 2017 study found that “nonfilers” were more likely to be seniors or recipients of public assistance than those who filed a tax return.

To provide direct cash payments to nonfilers, lawmakers could consider providing such payments through existing programs for certain vulnerable populations. To assist lawmakers in assessing the merits of such a proposal, this Insight examines the 2009 Economic Recovery Payment (ERP), which was a one-time \$250 payment made to most individuals who received recurring cash benefits from the Social Security Administration (SSA), the Railroad Retirement Board (RRB), or the Department of Veterans Affairs (VA).

OVERVIEW

The ERP was established as part of the American Recovery and Reinvestment Act of 2009 (ARRA; P.L. 111-5). Section 2201 of ARRA provided a one-time payment of \$250 to the following groups:

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11254, dated March 18, 2020.

- Adult Social Security beneficiaries;
- Supplemental Security Income (SSI) recipients of all ages;
- Adult railroad retirement annuitants; and
- Adult VA disability compensation or pension recipients.

The ERP was not available to dependent minor or student children who might otherwise receive benefits under Social Security, railroad retirement, or VA's programs, nor was it available to SSI recipients who received a personal needs allowance.

To qualify, an individual must have been eligible for benefits under one of the aforementioned programs for at least one month during the three-month period prior to ARRA's enactment (i.e., eligible for benefits between November 2008 and January 2009). Individuals were ineligible for the ERP if they resided outside of the United States or had their benefits suspended during the qualifying month prior to ARRA's enactment because they were (1) incarcerated, (2) a fugitive felon, (3) a probation or parole violator, (4) not lawfully present in the United States, or (5) found to have committed fraud.

Each eligible individual received the ERP. Thus, a married couple composed of two eligible individuals received \$500 in combined payments (\$250 each). However, ARRA specified that no eligible individual could receive more than one payment, even if he or she were eligible for benefits under multiple programs (e.g., Social Security and VA disability compensation). In addition, the ERP reduced the amount of the Making Work Pay tax credit, which was another stimulus measure in ARRA.

ARRA specified that the ERP was not subject to federal income tax, and it provided the ERP with certain garnishment protections, although the ERP was still subject to the Treasury Offset Program. ARRA also provided that the ERP could not be treated as income, or as a resource for the month of receipt and the following nine months, in determining the individual's eligibility or assistance amount under any federally funded public program. ERPs and administrative costs were financed by general revenues.

LEGISLATIVE HISTORY AND RATIONALE

The House version of ARRA would have provided for a one-time payment to SSI recipients equal to the average monthly SSI payment. In justifying the payment, Representative Carolyn Kilpatrick noted that ARRA "focuses on addressing the needs of those who need assistance most" and SSI recipients would be more likely to spend the payment quickly because they have "very low incomes."

The Senate version of ARRA would have set the one-time payment equal to \$300 and extended it to Social Security, RRB, and VA beneficiaries. Then-Senate Finance Committee chairman Max Baucus said the provisions in ARRA (including the one-time payment) were designed to "counteract weak consumer demand and spending slowdowns."

The conference agreement followed the Senate version but set the payment level at \$250. Representative Paul Kanjorski remarked that by providing the ERP to retirees and disabled individuals, the payment was designed to "help more people without jobs." Meanwhile, Senator Sheldon Whitehouse noted that the ERP provided "extra help from the Federal Government" for vulnerable seniors.

IMPLEMENTATION

ARRA required SSA, RRB, and VA to work with Treasury to coordinate and certify the eligibility of each ERP recipient. Administering agencies sent out notices to identified individuals in advance of receiving the ERP, as well as provided FAQs on their websites.

Treasury was required to start disbursing ERPs no later than 120 days (4 months) after enactment of ARRA (February 17, 2009), and no payments were to be made after 2010. Treasury disbursed most ERPs in May 2009, as well as a “catch-up” payment in December 2010 for individuals identified as eligible after the initial disbursement date (*Table 1*). SSA considered the May 2009 timeframe to be “a major accomplishment,” given the short statutory deadline for initial payments. Treasury ultimately issued more than 55.2 million ERPs, totaling over \$13.8 billion.

Table 1. Economic Recovery Payment (ERP) schedule

Milestone	Completion Date	Days Since Enactment of ARRA (Feb. 17, 2009)
First Social Security payments	05/07/2009	79
SSI payments	05/18/2009	90
Last Social Security payments	05/28/2009	100
RRB payments	05/29/2009	101
VA payments	06/30/2009	133
“Catch-up” payments	12/31/2010	682

Source: U.S. Department of the Treasury.

DISCUSSION

The congressional rationale for the ERP was twofold: (1) to provide assistance to certain vulnerable populations and (2) to stimulate economic activity through consumer spending. A 2012 study analyzed the answers to a 2009 household survey on certain stimulus measures created in 2008 and 2009. It found that most ERP recipients were aged 65 or older, had household income at or below \$35,000, and had little or no wealth in stocks. With respect to how recipients used the ERP, the study found that 30% mostly spent it, 29% mostly saved it, and 41% mostly paid down debt with it.

Chapter 410

COVID-19 AND STIMULUS PAYMENTS TO INDIVIDUALS: HOW DID THE 2008 RECOVERY REBATES WORK?*

Margot L. Crandall-Hollick

In response to concerns about an economic slowdown stemming from the COVID-19 pandemic, policymakers have been considering a broad array of policy options. Some are targeted directly toward individuals and industries that may be most affected. Others would more broadly seek to stimulate the economy. Among this latter category of policies, some have proposed direct cash payments sent to virtually all U.S. households.

In 2008 Congress enacted direct cash payments—the 2008 recovery rebates—that were tax credits advanced to households that had filed an income tax return. A portion of these credits were refundable and hence available to taxpayers with little to no income tax liability, including many low-income filers. (For answers to some common questions about advanced refundable tax credits, see CRS Insight IN11247).

This Insight provides a brief overview of how those 2008 recovery rebates worked.

2008 RECOVERY REBATES

On January 28, 2008, the House introduced H.R. 5140, which was enacted into law as P.L. 110-185 two weeks later. The law included 2008 recovery rebates for individuals that were credits against 2008 income taxes. The recovery rebate for a given taxpayer was equal to (1) a \$300-\$600 basic credit amount per individual, plus (2) an additional \$300 per-child credit amount. These credit amounts were phased out for higher-income taxpayers.

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11255, dated March 19, 2020.

CALCULATING THE CREDIT AMOUNT

The basic credit was equal to the greater of the following:

- the taxpayer's *net income tax liability* up to \$600 (\$1,200 for married joint filers). Net income tax liability was effectively pre-EITC and pre-child tax credit income tax liability—or
- \$300 (\$600 for married joint filers) if the taxpayer had *qualifying income*. For the purposes of the basic credit, qualifying income was either (a) at least \$3,000 in total of some combination of earned income, social security income, or veterans' benefits, or (b) gross income above the taxpayer's standard deduction plus a personal exemption (two personal exemptions for married joint filers) and \$1 of net income tax liability.

The child credit was \$300 for each of the taxpayer's children that qualified for the permanent child tax credit. Taxpayers could only receive the supplementary child credit if they were eligible to receive the basic credit.

The total credit—basic credit plus child credit—was phased out at a rate of 5% of adjusted gross income (AGI) above \$75,000 (\$150,000 for married joint returns). Higher-income taxpayers not subject to the phaseout would tend to receive a larger basic credit, while lower-income taxpayers would tend to receive a smaller basic credit.

OTHER PROVISIONS OF THE 2008 RECOVERY REBATES

- *SSN Requirement*: Taxpayers had to provide social security numbers (SSN) for themselves, their spouse (if married filing jointly), and any child for whom they claimed the supplementary child credit. Taxpayers who provided an individual taxpayer identification number (ITIN) were ineligible for the credit.
- *Nonresident Aliens*: The credit was not available to nonresident aliens.
- *Territories*: The law included a provision requiring the U.S. Treasury to make payments to territories (mirror code and non-mirror code) equal to the aggregate amount of credits claimed by their residents.
- *Interaction with Means-Tested Programs*: 2008 recovery rebates were not included in income (for the month they were received and the following two months) in determining eligibility for, or the amount of, any federally funded public benefit program. (A similar provision is now permanent law for all refundable credits.)
- *Subject to Offset for Past-Due Debts*: All or part of an economic stimulus payment could be applied to back taxes or certain other debts of the taxpayer, such as delinquent child support and student loans.

ADVANCING THE 2008 RECOVERY REBATES

The law also included a provision to advance the credit during 2008. Without this advancing provision, taxpayers would have received the recovery rebates when they filed their 2008 income tax returns in early 2009.

The advanced credit amount was estimated using the same formula as the 2008 recovery rebates, but based on taxpayers' 2007 income tax return information. Hence, the IRS evaluated information on taxpayers' 2007 returns, determined the credit amount as described above, and began to advance the recovery rebate by the end of April 2008. Taxpayers that had filed their 2007 tax returns and received a refund via direct deposit also received the 2008 recovery rebates via direct deposit. (They also generally received their advanced recovery rebate within two weeks of payments going out.) Otherwise, paper checks were mailed out to taxpayers using address information collected from their 2007 income tax returns. In other words, taxpayers had to file a 2007 income tax return in order to receive the recovery rebate check in 2008.

However, taxpayers that did not receive the advanced credit, perhaps because they did not file a 2007 income tax return, could receive it when they filed their 2008 income tax return at the beginning of 2009.

According to the Treasury Inspector General for Tax Administration (TIGTA), "The IRS issued more than \$96 billion in advanced economic stimulus payments to more than 119 million individuals in Calendar Year 2008 and approximately \$8.5 billion in recovery rebate credits to almost 21 million taxpayers as of April 17, 2009."

If taxpayers received a larger advanced credit in 2008 than they were eligible for, they *were not* required to repay the excess credit. For example, if a single parent had \$600 in net income tax liability and one qualifying child in 2007, the IRS would advance the taxpayer a \$900 recovery rebate (\$600 basic credit plus the \$300 supplemental child credit). If, in 2008, the taxpayer's income tax liability remained the same, but their child actually ended up living with their ex-spouse—and therefore was not the taxpayer's qualifying child for the \$300 supplementary child credit in 2008—their actual recovery rebate would have been \$600, a \$300 difference. However, under the law, the taxpayer would not need to pay back this excess amount.

Chapter 411

COVID-19 AND STIMULUS PAYMENTS TO INDIVIDUALS: POTENTIAL IMPACTS OF DIRECT PAYMENTS ON FAMILY INCOMES*

Conor F. Boyle and Jameson A. Carter

Several Members of Congress and the Trump Administration have proposed direct cash payments as part of a fiscal response to the economic impacts of the COVID-19 pandemic. Direct cash payments have previously been part of the federal government's response to economic downturns, most recently in 2001 and 2008. In general, the purpose of direct payments is twofold: (1) they allow families to spend more, and through a multiplier effect help to stimulate the economy; and (2) they provide resources to help meet basic needs for those whose income has decreased due to COVID-19 infection or potential job loss. This Insight discusses several current direct payment proposals and their impact on family incomes.

WHAT DIRECT PAYMENT PROPOSALS ARE CURRENTLY BEING DISCUSSED?

Members of both parties, as well as the Trump Administration, have proposed some form of direct payments. These proposals vary in terms of who is eligible to receive a payment, the per-person amount to be paid, and whether payments would be one-time or recurring. Selected direct payment proposals include the following:

- a one-time payment of \$1,000 per adult proposed by Senator Romney,
- up to two payments of \$1,000 per adult and \$500 per child proposed by the Trump Administration, and

* This is an edited, reformatted and augmented version of Congressional Research Service Publication No. IN11261, dated March 20, 2020.

- a proposal from Senators Bennet, Brown, Booker, King, Murphy, and Schatz to provide recurring payments of \$2,000 per individual (adult and child) that would gradually phase down as economic conditions improve.

When considering direct payment proposals, one question is how payments would be delivered to eligible Americans. In both 2001 and 2008, direct payments were provided as advance refundable tax credits received as a direct deposit or a check in the U.S. mail. Because these payments were made through the tax system, eligible individuals who did not file an income tax return the previous year did not receive a payment. In the past, the federal government has also provided additional direct payments to individuals who receive recurring benefits such as Social Security or pensions through the Department of Veterans Affairs. (Note that while some proposals may provide payments to taxpayers, this analysis is of families, which may include more than one taxpayer.)

HOW MUCH WOULD FAMILY INCOMES INCREASE DUE TO A DIRECT PAYMENT?

Policymakers may wish to consider the extent to which a direct payment could increase family income. To estimate the potential impact of a direct payment, CRS calculated the amount that families would receive under each of the three proposals noted above. CRS then compared the estimated benefit a family would receive to their estimated monthly income. *Table 1* presents families' median estimated monthly income and the median percentage of monthly income that families would receive under the direct payment proposals. These estimates are broken down by the ratio of family income to the poverty threshold in order to show the impacts of direct payment proposals across the income distribution.

The estimates presented in *Table 1* suggest that all three of the direct payment proposals would provide families with a substantial amount of their prior estimated monthly income. This effect is particularly strong for lower-income families. *Table 1* presents estimates at a high level, and does not convey variations in the impact of direct payments based on factors such as family size, family structure, and age.

These estimates should be considered with a number of caveats in mind. This analysis (1) assumes that every eligible family would receive exactly the benefit to which it is entitled, (2) does not phase down payments to higher-income families, (3) estimates monthly income using an annual measure and does not reflect potential month-to-month fluctuations in family income, and (4) does not estimate decreases in income that families may experience as a result of COVID-19.

Other analysis of direct payment proposals returns estimates that are similar to the ones presented in this analysis, but are methodologically different in several important ways. First, this analysis uses a broader definition of family income that includes additional sources of income and benefits. Second, this analysis breaks families into groups based on the ratio of family income to poverty rather than using deciles of taxable income. Finally, this analysis estimates *median* increases rather than average (or mean) increases in income.

Table 1. Median percentage of estimated monthly income families would receive under three proposed direct payments

Ratio of Family Income to Poverty	Median Estimated Monthly Income (current law)	Median Percentage of Estimated Monthly Income Families Would Receive if Payment is \$1,000 per Adult	Median Percentage of Estimated Monthly Income Families Would Receive if Payment is \$1,000 per Adult and \$500 per Child	Median Percentage of Estimated Monthly Income Families Would Receive if Payment is \$2,000 per Individual
Under 100% (below poverty)	\$850	137%	153%	337%
100%-199%	\$2,100	69%	80%	177%
200%-299%	\$3,570	44%	49%	105%
300%-399%	\$4,930	32%	36%	77%
400%-499%	\$6,240	26%	29%	60%
500% and above	\$10,440	16%	17%	36%
Total	\$3,600	42%	48%	104%

Source: CRS calculations via the TRIM3 microsimulation model using 2016 data.

Notes: Median estimated monthly income rounded to the nearest ten. Estimated monthly income was calculated by dividing families' annual income by 12. Income reported in this analysis reflects the Supplemental Poverty Measure (SPM) definition of income, and includes a family's after-tax wage income, self-employment income, the value of refundable tax credits, Social Security, Supplemental Security Income (SSI), Supplemental Nutrition Assistance Program (SNAP), assisted housing benefits, child care subsidies, and more. SPM poverty thresholds were used to calculate the ratios of family income to poverty.

WHAT ARE THE ALTERNATIVES TO DIRECT PAYMENTS?

Some commentators have noted that direct payments are not necessarily targeted at the families most impacted by COVID-19. Social insurance programs such as unemployment compensation, workers' compensation, and disability insurance are well established and may be more effective at targeting benefits to families impacted by the virus or an associated economic downturn. The Temporary Assistance for Needy Families (TANF) program has also been used in previous economic downturns to provide short-term benefits to families with immediate needs.

Chapter 412

COVID-19 AND DIRECT PAYMENTS TO INDIVIDUALS: HISTORICAL PRECEDENTS*

Gene Falk

ABSTRACT

Members of Congress and the Trump Administration have signaled their support for making direct payments to individuals to address the economic fallout from the COVID-19 outbreak. In current discussions, these payments are sometimes framed in terms of “universal basic income” or UBI proposals. In the past when these proposals were made—and sometimes enacted—they were framed in terms of providing economic stimulus.

HISTORICAL PRECEDENTS

There are historical precedents for such payments; most of these were done through the federal income tax code. The Internal Revenue Service (IRS) sent checks to taxpayers in 1975, 2001, and 2008. An issue with using the IRS to make payments to individuals is that payments generally have been restricted to those who file federal income tax returns. Those who do not file tax returns generally include populations such as retirees, disabled individuals, and low-income individuals who have no earnings. The 1975 legislation included direct payments to retirees receiving Social Security and Railroad Retirement. In 2009, direct payments were also made to retirees, recipients of Supplemental Security Income (SSI), and recipients of certain veterans’ benefits.

Table 1 provides an overview of laws enacted since 1975 that provided for one-time payments to individuals to address economic downturns.

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. IN11256, dated March 19, 2020.

Table 1. Selected law providing direct payments to individuals: 1975 to present

Law	Description	CRS Products
Tax Reduction Act of 1975 (P.L. 94-12)	Tax rebate: 10% of taxes paid in 1974. Maximum payment of \$200 (phased down to \$100 for higher income taxpayers). Direct payment: \$50 for Social Security and Railroad Retirees and recipients of Supplemental Security Income (SSI).	CRS Report 92-20E (available to congressional clients upon request).
The Economic Growth and Tax Relief Reconciliation Act of 2001 (P.L. 107-16)	Advance payment of a tax rate reduction. Maximum credit of \$600 for married couples filing jointly and \$300 for others.	CRS Report RS21171, <i>The Rate Reduction Tax Credit - "The Tax Rebate" - in the Economic Growth and Tax Relief Reconciliation Act of 2001: A Brief Explanation</i>
Economic Stimulus Act of 2008 (P.L. 110-185)	Advance payment of a refundable tax credit. Maximum credit of \$1,200 for joint filers, \$600 for others, and an additional \$300 per dependent. Credits phased out for higher income taxpayers.	CRS Insight IN11255, <i>COVID-19 and Stimulus Payments to Individuals: How Did the 2008 Recovery Rebates Work?</i>
American Recovery and Reinvestment Act of 2009 (P.L. 111-5)	Payment of \$250 for certain recipients of Social Security, Supplemental Security Income (SSI), Railroad Retirement, and veterans' compensation or pensions.	CRS Insight IN11254, <i>COVID-19 and Stimulus Payments to Individuals: How the 2009 Economic Recovery Payment Worked.</i>

Source: Congressional Research Service (CRS).

The economic effects of past direct tax payments have been studied (see summaries here and here). Also see here for a discussion of how direct payments may compare with an alternative to provide payroll tax relief.

RELATIONSHIP TO UNIVERSAL BASIC INCOME AND AUTOMATIC PAYMENTS

The current discussions about these payments are sometimes framed as a “universal basic income” or UBI. UBI is a form of guaranteed income that would provide a payment to individuals or families at regular intervals. The United States does not have an income guarantee other than the Supplemental Security Income program (SSI), which is restricted to the needy aged, blind, and disabled. SSI was created in 1972 in legislation related to President Nixon’s proposal to create a guaranteed income for families with children, his Family Assistance Plan (FAP).

Social insurance benefits—particularly unemployment compensation—provides partial wage replacement for some workers who lose their jobs. Need-tested programs provide benefits to low-income individuals and families, though benefits are restricted to certain categories of low-income persons, and not all persons who are eligible receive aid. The programs that aid the largest number of low-income persons— the Supplemental Nutrition Assistance Program (SNAP) and Medicaid—provide in-kind rather than cash aid. Cash aid provides families and individuals with the greatest flexibility to address their individual circumstances, whether that is paying rent, bills, child care, or other necessities.

Prior to the current situation, Claudia Sahm, formerly an economist at the Federal Reserve Board, proposed in May 2019 automatic direct payment in the event of a recession. She proposed that direct payments be triggered by a rise in the unemployment rate by a sufficient amount.

Chapter 413

COVID-19: CYBERCRIME OPPORTUNITIES AND LAW ENFORCEMENT RESPONSE*

Kristin Finklea

Opportunistic criminals and other malicious actors exploit the internet and rapidly evolving technology to their advantage. Criminals can compromise financial assets; hacktivists can flood websites with traffic, effectively shutting them down; and spies can steal intellectual property and government secrets. And, they capitalize on ever changing world events. Federal officials have cautioned about scams relating to the outbreak of disease caused by a previously unidentified strain of coronavirus, designated Coronavirus Disease 2019, or COVID-19. They have noted that “[c]yber actors may send emails with malicious attachments or links to fraudulent websites to trick victims into revealing sensitive information or donating to fraudulent charities or causes.”

Indeed, analysts and officials have reported criminals using public interest in COVID-19 to their advantage. For instance, the Department of Justice (DOJ) cites “reports of individuals and businesses selling fake cures for COVID-19 online and engaging in other forms of fraud, reports of phishing emails from entities posing as the World Health Organization or the Centers for Disease Control and Prevention, and reports of malware being inserted onto mobile apps designed to track the spread of the virus.” In one scheme reported by security experts, hackers sold a malware infection kit that used an interactive map of coronavirus infections produced by Johns Hopkins University. The kit was designed to spread malware to steal passwords.

CYBERCRIME INVESTIGATIONS

Federal law enforcement has the principal role in investigating and attributing cyber incidents, including those that may take advantage of heightened public interest in the

* This is an edited, reformatted and augmented version of a Congressional Research Service publication IN11257, prepared for Members and Committees of Congress dated March 19, 2020.

COVID-19 pandemic, to specific perpetrators, and this responsibility has been codified within the broader framework of federal cyber incident response. Specifically, DOJ—through the Federal Bureau of Investigation (FBI) and National Cyber Investigative Joint Task Force (NCIJTF)—is the designated lead in responding to these threats.

FBI Cyber Investigations

The FBI pursues cybercrime cases ranging from computer hacking and intellectual property rights violations to child exploitation, fraud, and identity theft. Its top cyber priorities involve combating computer and network intrusions and investigating ransomware. The FBI's cyber efforts are focused on “high-level intrusions by state-sponsored hackers, global organized crime syndicates, and other technically sophisticated and dangerous actors.”

One key challenge involves moving away from reacting to malicious cyber events and toward preventing them. As such, the FBI has focused resources on enhancing cyber capabilities in a number of ways, including bolstering the FBI's cyber workforce, strengthening the NCIJTF, expanding Cyber Task Forces (CTFs) and focusing their efforts on computer/network intrusion investigations, and increasing information sharing and coordination with the private sector.

Task Forces and Partnerships

The NCIJTF was established by National Security Presidential Directive-54/Homeland Security Presidential Directive-23 in January 2008. The NCIJTF's mission is to “serve as a multi-agency national focal point for coordinating, integrating, and sharing pertinent information related to cyber threat investigations.” Led by the FBI, the NCIJTF coordinates over 20 federal agencies, including law enforcement, intelligence, and the military. It also collaborates with the private sector and international partners. Early on, there were concerns that “the NCIJTF was not always sharing information about cyber threats among the partner agencies.” There were also criticisms that the NCIJTF was perceived as an extension of the FBI's Cyber Division instead of as a multiagency effort. However, DOJ's Inspector General has since noted that these issues have improved.

The FBI leads several other task forces and partnerships focused on cyber threat response. For instance, there is a CTF at each field office. CTFs focus on local cybersecurity threats, respond to incidents, and maintain relationships with companies and institutions. CTFs also support the national effort to combat cybercrime by participating in national virtual teams on certain cyber issues and providing cyber subject matter experts or enhanced capability outside of their assigned areas, when needed. Additionally, the FBI has established and maintained Cyber Action Teams of agents and computer scientists that can be rapidly deployed around the world to assist in computer intrusion investigations. In addition to domestic field offices pursuing international leads in investigations, the FBI has positioned cyber assistant legal attachés (ALATs) in some foreign countries. ALATs work with law enforcement in host countries to share information, collaborate on investigations, and enhance

relationships with partner agencies. ALATs focus on “identifying, disrupting, and dismantling cyber threat actors and organizations.”

GOING FORWARD: DOJ CYBER PRIORITIES

Countering cyber threats is among DOJ’s top priorities, and countering threats related to the COVID-19 pandemic is receiving heightened attention. On March 16, 2020, Attorney General William Barr issued a memorandum to the U.S. Attorneys regarding DOJ’s COVID-19 priorities. Noting that criminals may take advantage of the COVID-19 pandemic, the memorandum stated that “[e]very U.S. Attorney’s Office is thus hereby directed to prioritize the detection, investigation, and prosecution of all criminal conduct related to the current pandemic.” Congress, in examining DOJ’s cyber priorities going forward, may look to the resources DOJ has placed toward countering cyber threats broadly as well as specific nefarious activity capitalizing on the COVID-19 pandemic.

DOJ has highlighted a number of challenges that law enforcement faces in countering cybercrime, and Congress may continue to conduct oversight and debate legislation in these arenas, including the following:

- **Transnational Crime.** Cybercriminals have specialized their activities and, because they can operate anywhere in the world, networks of expert cybercriminals—and digital evidence of their activity—may exist in various countries. There are sometimes investigative challenges in gathering evidence, working with international law enforcement, and bringing perpetrators to justice in the United States.
- **Evolving Technology.** While some note that law enforcement may have access to more digital information than ever before, others contend that law enforcement is “going dark” as some investigative capabilities are outpaced by the speed of technological change. These hurdles for law enforcement reportedly include strong, end-to-end (or what law enforcement has sometimes called “warrant-proof”) encryption, which can prevent access to certain communications and information. The tension between privacy of electronic communications and law enforcement’s ability to investigate crimes remains of congressional interest.

Chapter 414

COVID-19 AND BROADBAND: POTENTIAL IMPLICATIONS FOR THE DIGITAL DIVIDE*

Colby Leigh Rachfal

ABSTRACT

According to the Federal Communications Commission's (FCC) 2019 Broadband Deployment Report, approximately 21.3 million Americans lack a broadband connection speed of at least 25 megabits per second (Mbps) download/3 Mbps upload, which is the FCC's benchmark for high-speed broadband. In the midst of the coronavirus (COVID-19) pandemic, federal, local, and state governments, in addition to large and small businesses, are considering remote working or distance learning options to help abate the spread of the virus. As these decisions are made, some portion of the population will likely have the option and the capability to shift activities online, while others will not. COVID-19 mitigation efforts will likely reveal discrepancies in broadband availability and accessibility—termed the digital divide—across the United States.

THE DIGITAL DIVIDE

The term digital divide refers to the gap between those Americans who use or have access to telecommunications and information technologies and those who do not. Several factors contribute to the digital divide disparity, including terrain, population density, demography, and market factors. Even in areas with broadband penetration, factors such as income can inhibit the ability of individuals to access broadband. For example, according to a 2019 Pew Research Center study, 44% of adults with household incomes below \$30,000 a year do not have home broadband services. Although broadband access in the United States

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. IN11239, dated March 13, 2020.

has steadily increased over the last 10 years, the digital divide persists. For background on the digital divide, see CRS Report RL30719, *Broadband Internet Access and the Digital Divide: Federal Assistance Programs*, by Colby Leigh Rachfal and Angele A. Gilroy.

REMOTE WORKFORCE CHALLENGES

Moving an entire workforce from an onsite environment to a remote environment may present some challenges; including the ability to connect to broadband in the home and the inability of all jobs to be done remotely. While those who have access to broadband may be able to work remotely and continue operations uninterrupted, there are many people who cannot perform their work functions from home, such as those in the restaurant, construction, or hospitality industries. According to the Department of Labor, approximately 29% of workers in the United States may be able to work from home. Another challenge may be capacity issues and whether a network can support a remote workforce.

DISTANCE LEARNING AND THE HOMEWORK GAP

Internet use has increased in schools, with a growing number of schools issuing homework assignments online. In response to the coronavirus, some schools are not just assigning homework online, but temporarily moving all instruction online. The move to online instruction on a massive scale will likely encounter various challenges, especially if students do not have access to broadband at home or access to service with sufficient speed to support live features such as video conferencing. The divide between students that have access to adequate broadband at home and those that do not is known as the *Homework Gap*. While some schools may have the option to shift classes online, many cannot due in part to the varying levels of access to broadband. Some schools may have the resources to lend devices, such as laptops or tablets, along with hotspots to provide broadband to students; however, some schools may not—which may place those students at a potential disadvantage to their peers who do have connectivity.

TELEMEDICINE

As the coronavirus continues to spread in the United States, the Centers for Disease Control and Prevention (CDC) have advised the best way to prevent catching the coronavirus is to avoid being exposed to the virus; namely avoiding close contact with people who may be carrying the virus (also known as social distancing). Visiting a doctor's office may increase the chance of encountering people who are contagious, and an option of seeing a doctor virtually, known as telemedicine, may be an effective method of reducing the spread of the coronavirus. In addition, the coronavirus may constrain resources at hospitals and telemedicine could be an efficient and safe way for doctors to diagnose patients. By using the telemedicine option, a patient may be able to video teleconference with a doctor from the comfort of their home; however, telemedicine requires connection to high-speed broadband.

For background on telemedicine, see CRS Report R46239, *Telehealth and Telemedicine: Frequently Asked Questions*, by Victoria L. Elliott.

BROADBAND MAPPING

Although the FCC's 2019 Broadband Deployment Report indicates approximately 21.3 million Americans lack a broadband connection, the number may be higher due to potential inaccuracies in broadband mapping data. Pinpointing where broadband is and is not available in the United States has been an ongoing challenge. Current data on national broadband availability is provided by private telecommunications providers, collected by the FCC, and displayed on the FCC's Fixed Broadband Deployment Map. Difficulty in accurately mapping broadband availability has been attributed to a number of factors, including the adequacy of census block data, the lack of independent data validation outside the FCC, and the absence of a challenge process for consumers and other entities that believe the Fixed Broadband Deployment Map may overstate availability in their area. This can be particularly challenging for decision-making on whether to move classes online or move a workforce to telework, as there is no accurate basis for determining who would have access to broadband and who would not. For additional information on broadband data and mapping, see CRS Report R45962, *Broadband Data and Mapping: Background and Issues for the 116th Congress*, by Colby Leigh Rachfal.

Chapter 415

COVID-19: POTENTIAL ROLE OF NET OPERATING LOSS (NOL) CARRYBACKS IN ADDRESSING THE ECONOMIC EFFECTS*

Mark P. Keightley

ABSTRACT

A number of industries may suffer losses in 2020 as a result of the coronavirus disease 2019 (COVID-19) outbreak. The travel and tourism industry, and restaurant industry, appear particularly susceptible at the moment due to an uptick in canceled reservations and a reduction in bookings. Other industries are likely to be impacted as well by a drop-off in consumer spending and a resulting reduction in profits, with the impacts likely increasing if COVID-19 continues to spread.

Before 2018, businesses with losses could “carry back” net operating losses (NOL) and use them to receive a refund for past taxes paid. On several occasions, Congress temporarily extended or enhanced the carryback rules to assist businesses in times of general economic weakness, or in response to natural disasters. Recent changes enacted in the 2017 tax revision (P.L. 115-97), commonly referred to as the Tax Cuts and Jobs Act (TCJA), however, eliminated the ability to carry back losses. This Insight discusses how allowing NOL carrybacks could potentially assist businesses impacted by economic weakness associated with COVID-19.

CARRYBACKS AND CARRYFORWARDS

When a business experiences a loss (or NOL, in tax jargon) it owes no tax in that year. Currently, a business may use a loss to reduce future taxes by claiming it as a deduction against income earned in some future year. This process is known as carrying forward a loss, and a business may carry a loss forward indefinitely. Prior to the TCJA, businesses were able

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. IN11240, dated March 16, 2020.

to use losses to obtain a refund for taxes paid in the past two years, a process known as carrying back a loss. TCJA, however, eliminated the two- year carryback. Businesses generally prefer to carry losses back rather than carry them forward because carrybacks produce a benefit sooner and with certainty, whereas carryforwards reduce taxes at some uncertain time in the future.

An example may help demonstrate the mechanics of carrying back a loss. Suppose that a business earned profits of \$100 last year and paid taxes of \$21 (i.e., the tax rate was 21%). This year the business incurred a loss of \$40 and thus owes nothing in taxes. If the business is allowed to carry back this \$40 loss it can receive a partial refund for taxes paid last year. It does this by recalculating its tax liability last year, subtracting the \$40 loss from its \$100 in income and applying the 21% tax rate. The business would find its recalculated tax liability for last year to be \$12.60 ($\$60 \times 21\%$). It would then receive as a refund the difference between what it originally paid in taxes last year and its recalculated tax liability, or \$8.40 ($\$21 - \12.60).

EXPANDED NOL CARRYBACKS: PAST EXPERIENCE

At various times, the NOL carryback period was modified to provide temporary or targeted tax relief. For example, during the Great Recession, the American Recovery and Reinvestment Act of 2009 (P.L. 111-5) and Worker, Homeownership, and Business Assistance Act of 2009 (P.L. 111-92) temporarily extended the two-year carryback period to up to five years. In response to the destruction caused by Hurricanes Katrina, Rita, and Wilma, Congress passed the Gulf Opportunity Zone Act of 2005 (P.L. 109-135), which extended the carryback period from two to five years for qualified losses occurring in the Gulf Opportunity Zone (or GO Zone). The Job Creation and Worker Assistance Act of 2002 (P.L. 107-147) temporarily extended the NOL carryback period from two to five years for losses incurred in 2001 and 2002 to assist in the economic recovery.

STIMULATIVE EFFECT OF LOSS CARRYBACKS

One feature of effective fiscal stimulus is the speed with which it can impact the economy. Loss carrybacks suffer from one fundamental issue in this aspect: losses cannot be carried back until after the end of the tax year. The reason is that tax losses are computed over a tax year, and not over a month or a quarter. Additionally, some businesses suffering from short-term economic disruption may not benefit from a NOL carryback if they earn a profit over their full year. Businesses that are reasonably confident that they will be in a loss position at the end of the tax year, and that have (or have access to) technical tax accounting expertise, may be able to adjust required estimated tax payments to reflect an expected loss carryback and experience some relief. These will most likely be larger corporate taxpayers, and not smaller businesses.

Still, because it is notoriously difficult to predict the economy's performance, and because there is a great deal of uncertainty about COVID-19, providing the ability to carry back losses may help support businesses if economic weakness is prolonged. Businesses that

ultimately incur losses at the end of the tax year would be able to amend previous years' tax returns and receive a partial refund. This could assist businesses that struggled to make payroll or cover operating expenses, as well as those that took loans that need to be repaid.

Another aspect of effective fiscal stimulus is the “bang for the buck” a given tax reduction or spending increase produces. Economists quantify this notion with the use of fiscal “multipliers.” Fiscal policy multipliers measure the change in economic output in response to a dollar change in taxes or a dollar change in spending. Past estimates by the Congressional Budget Office (CBO) and Moody's Analytics suggest that the multiplier effects associated with NOL carrybacks are small when compared to other policy options. CRS Report R45780, *Fiscal Policy Considerations for the Next Recession*, contains the CBO's and Moody's estimates, and also reviews the potential effectiveness of a number of fiscal stimulus options that have been considered in response to recent economic slowdowns, including NOL carryback modifications.

Separate from the stimulative effects of NOL carrybacks is the issue of whether carrybacks should be part of the tax system's underlying structure. Many economists would argue that allowing businesses to carry back losses increases economic efficiency by reducing the distorting effect taxation has on investment.

Chapter 416

USDA DOMESTIC FOOD ASSISTANCE PROGRAMS’ RESPONSE TO COVID-19: HOUSE-PASSED H.R. 6201 AND RELATED EFFORTS*

Randy Alison Aussenberg and Kara Clifford

ABSTRACT

U.S. Department of Agriculture (USDA) Food and Nutrition Service (FNS) programs are often part of emergency response efforts, providing program flexibilities, foods for distribution, and benefits for redemption. Emergencies generate different FNS responses and vary with states’ requests. During the COVID-19 pandemic, access to food—particularly in light of school closures—has been a concern for many. Some also view the Supplemental Nutrition Assistance Program (SNAP) as a force for economic stimulus. This Insight discusses House-passed H.R. 6201’s food assistance provisions, which supplement FNS’s existing COVID-19 response with new funds and authorities.

USDA-FNS RESPONSES TO-DATE

FNS maintains a COVID-19 response website.

During unanticipated school closures, school districts or “school food authorities” that normally operate the National School Lunch Program and School Breakfast Program may transition to serving meals through the Summer Food Service Program (SFSP) or Seamless Summer Option (SSO) if they are approved as summer meal sponsors. Nonprofit and other public agency sponsors may also operate meal sites, and states may approve new sponsors, during unanticipated school closures.

Normally, SFSP/SSO meals must be served at non-school sites and consumed onsite (“congregate feeding”). As of March 15, 2020, USDA-FNS had granted waivers to all 50

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. IN11250, dated March 18, 2020.

states, DC, and Puerto Rico, allowing SFSP/SSO operators to serve meals in non-congregate settings (e.g., meal pick-up or delivery) and at school sites during COVID-19-related school closures.

For SNAP's Quality Control system, FNS is allowing telephone interviews instead of face-to-face interviews in 16 states as of March 15, 2020.

SUPPLEMENTAL APPROPRIATIONS FOR WIC AND TEFAP (DIVISION A)

H.R. 6201 provides a \$500 million supplemental appropriation for the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC). It also provides a \$400 million supplemental appropriation for The Emergency Food Assistance Program (TEFAP), of which \$100 million can be used for food distribution costs.

CHILD NUTRITION PROGRAMS (§§2102, 2202)

Under §12(l) of the Richard B. Russell National School Lunch Act (42 U.S.C. §1760(l)), states and service providers may request, and USDA may grant, waivers of child nutrition program requirements. Division B of H.R. 6201 expands these authorities.

§2102 newly allows USDA to grant waivers that increase federal costs. Such waivers must be requested by a state or service provider and be aimed at providing meals and snacks during a COVID-19-related school closure.

§2202 newly allows USDA to issue a single waiver to all states. States may opt-in without USDA's approval. §2202 also specifies that USDA may grant waivers to allow non-congregate feeding in the Child and Adult Care Food Program. Both waivers must be for the purpose of providing meals and snacks "with appropriate safety measures with respect to COVID-19."

§2202 also newly allows USDA to grant waivers related to the nutritional content of meals served in child nutrition programs if USDA determines the waiver is necessary to provide meals and snacks and there is a food "supply chain disruption" due to COVID-19.

The waiver authority under §2202 expires on September 30, 2020.

SNAP

SNAP Benefits during School Closures (§1101)

H.R. 6201 includes what has been called "P-SNAP" (Pandemic Supplemental Nutrition Assistance Program), an option allowing USDA approval of state plans to provide SNAP benefits, when a school is closed five or more days, to households with children who would normally receive free or reduced-price school meals (in an amount equal to at least five days' of free meal reimbursements).

This option was last available in FY2010 (during the H1N1 flu epidemic), enacted in an FY2010 appropriations law (P.L. 111-80, §746). In 2009, FNS issued detailed guidance. However, no SNAP state agencies ever administered P-SNAP.

Work-Related Requirements (§2301)

SNAP has work-related eligibility requirements, the strictest being a time limit for nondisabled adults (ages 18 to 49) without dependents (“ABAWDs”) who work less than 80 hours per month. §2301 suspends this time limit nationwide during the period of the Secretary of Health and Human Services’ public health emergency declaration, allowing participants who would have lost eligibility due to the time limit to continue to receive benefits.

Separately, on March 13, 2020, a federal court blocked enforcement of the part of a USDA final rule that would make it more difficult for states to use labor statistics to waive the time limit, changes that were to go into effect April 1. The court “determined that aspects of the Final Rule are likely unlawful ... [and]

USDA will be enjoined from implementing those aspects of the Final Rule nationwide pending final judicial review.” Part of the court’s rationale was the global pandemic.

Benefit Increases, Administrative Requirements (§2302)

§2302 provides for temporary SNAP benefit increases during the public health emergency. It requires USDA to grant SNAP state agencies’ requests that are supported “with sufficient data (as determined by [USDA]).” The increases are “to address temporary food needs not greater than the applicable maximum monthly allotment for the household size.” Previously, a nationwide increase to SNAP benefits was included in the American Recovery and Reinvestment Act of 2009 (P.L. 111-5).

The bill also allows USDA to adjust (through guidance and based on states’ requests) administrative requirements like issuance methods and reporting requirements.

WIC (§§2203, 2204)

In addition to the aforementioned supplemental funding provided, H.R. 6201 gives USDA further authority to grant waivers allowing WIC participants to get certified (or recertified) without being physically present at the WIC clinic (normally required). Waiver requests are to be made by state agencies to USDA.

Also, the bill authorizes USDA to grant waivers from program administrative requirements that a state determines “cannot be met due to COVID-19” and is “necessary to provide assistance” under WIC.

GRANTS FOR NUTRITION ASSISTANCE FUNDING FOR CERTAIN TERRITORIES (§1102)

The Northern Mariana Islands, Puerto Rico, and American Samoa do not operate a SNAP program; instead, they operate programs funded by Nutrition Assistance Program block grants in lieu of SNAP. §1102 provides \$100 million for grants to these territories for nutrition assistance “in response to a COVID-19 public health emergency,” as presumably they would not have the authority to operate P-SNAP or other options in the bill that increase SNAP benefits.

Chapter 417

COVID-19: THE POTENTIAL ROLE OF TANF IN ADDRESSING THE ECONOMIC EFFECTS*

Gene Falk

The Temporary Assistance for Needy Families (TANF) block grant provides grants to the 50 states, District of Columbia, American Indian tribes, and certain territories with the broad purpose of ameliorating and addressing root causes of childhood economic disadvantage. Some of the flexibility the block grant affords to states has been used, and augmented by federal legislation, to address the fallout from Hurricane Katrina and the deep economic recession of 2007-2009. TANF is currently funded on a short-term basis, with funding set to expire on May 22, 2020.

OVERVIEW OF TANF

TANF was created by the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 (PRWORA, P.L. 104-193) and is best known as funding for state programs that provide monthly assistance to needy families with children. PRWORA placed work requirements on states and time limits on families that receive this assistance. TANF funds a wide range of benefits and services—including what are known as “non-recurrent short-term benefits,” which are defined as aid that addresses a specific episode of need and does not exceed four months. The receipt of a nonrecurrent short-term benefit does not count toward a family’s time limit, nor other requirements such as those related to work, assigning child support to the state, and state reporting of detailed characteristics. In crafting a response to Hurricane Katrina in 2005, Congress enacted special rules to permit states to tap an existing fund to pay nonrecurrent short-term benefits to families evacuated from their homes because of Hurricane Katrina.

* This is an edited, reformatted and augmented version of a Congressional Research Service publication IN11241, prepared for Members and Committees of Congress dated March 16, 2020.

In terms of addressing unemployment related to a recession, TANF can also fund employment services and subsidized employment. If an individual is in subsidized employment, the requirements of assistance (e.g., time limits) also do not count.

TANF FUNDING

The basic TANF block grant provided to states was established in PRWORA in 1996, based on spending in its predecessor programs in the early 1990s. The basic block grant has not been adjusted for inflation or changes in other circumstances (e.g., population growths and shifts among the states). It represents the bulk of funding available to the states under TANF. Nationally, the assistance caseload is about 25% of what it was in the 1990s, and states have shifted TANF funds to a wide range of activities.

PRWORA also contained a \$2 billion contingency fund for economic downturns. However, that fund was exhausted in the last recession; in recent years, Congress has provided appropriations of \$608 million per year to it. The fund is spent each year regardless of economic conditions. It is expected to be exhausted in April of this year. Thus, there is little in the way of additional federal funding for states to meet unexpected costs related to COVID-19.

States also have the ability to “reserve” (save) TANF funding. Some states have relatively large reserves, others have no reserves.

POTENTIAL LEGISLATION TO ADDRESS THE EFFECTS OF THE COVID-19 OUTBREAK

The flexibility of states’ use of TANF make it a possible source of funding for them to address the unknown and evolving needs of families resulting from the COVID-19 pandemic. However, states may not have funds to meet *unexpected* costs. Moreover, the fund that was tapped to provide states with help to address Hurricane Katrina is in the process of being exhausted for the current fiscal year.

Congress responded to the economic downturn of 2007-2009 by creating a separate emergency fund. Such a fund to provide for increased short-term benefits would be an option to address the immediate economic needs of families resulting from the COVID-19 pandemic. Further, Congress might consider addressing not only these emergency needs, but also the lack of a counter-cyclical funding mechanism for states under TANF. That is, if the economy does go into recession, there is no automatic TANF funding to address it. The emergency fund created for the 2007-2009 recession might be considered a model for such a fund.

Additionally, Congress might consider addressing TANF work participation standards. These standards are rules for *states*, not individuals, and states are penalized if they do not have a sufficient number of families participating for a minimum number of hours per week. Thus, they do help guide how states set work requirements for individual recipients.

TANF regulations require that all hours that an individual is in paid employment—including paid sick leave—count toward meeting the hourly requirement. However, the

regulations limit to 16 hours per month excused absences from non-paid activities because of illness. States may excuse hours for individual recipients, providing “good cause” exemptions for those who are sick or caring for family members. However, this could disadvantage states in meeting their work participation standards. The U.S. Secretary of Health and Human Services may, but is not required to, provide a “reasonable cause” waiver of the penalty imposed on a state for failure to meet the TANF work requirements.

ABSTRACT

Corona virus disease 2019 (COVID19) emerged in December 2019 in China and has been a viral disease as it continues to spread in almost all the countries of the world. It has put us in unprecedented situation and has changed our daily activities. It has also forced us to find different ways in conducting our plans. There have been many researches on the COVID-19 conducted around the globe. Among of the many conducted research, we compiled some in this book. The aim of this book, therefore, is to share information and scientific evidence and to provide an overview of the COVID-19 in South East Asia and India.

Keywords: COVID-19

INTRODUCTION

On 11 February 2020, World Health Organization (WHO) announced a disease caused by a new coronavirus was a COVID-19, which is the acronym of corona virus disease 2019. This COVID-19 was first identified in Wuhan province, China in December 2019. According to the WHO, viral diseases continue to emerge and represent a serious issue to public health and

* Corresponding Author's Email: nandiyanto@upi.edu.

COVID-19 is one of them because it has claimed hundred thousands of lives worldwide (Anggraeni et al., 2020).

COVID-19 has put us the unprecedented situation where isolation has to be taken to lower the infection. People have to stay indoors and do the activities inside as much as possible. As a result, almost all aspects of our life have been affected from the economy, health, education, information and technology to social condition. At the time, we are working on book chapters, the COVID-19 is still haunting us, while throughout the world, scientists, government, and health authorities are working and making incredible efforts to find the cure for this virus. Others have been working to find ways to adapt to the new life. In Indonesia, in some areas, the government even imposed stricter social restrictions for the so-called “red zones” (Zuhairroh and Rosadi 2020). It also affects the economy which is shown by the potential for shocks in the demand and supply of goods and services (Machmud and Minghat 2020).

There was a significant increase in the number of publications on COVID-19 from 2019 to 2020 (Hamidah, Sriyono and Hudha 2020) such as its effects on vocational education (Ana 2020; Mulyanti, Purnama, and Pawinanto 2020). In the midst of this crisis, the authors of this book have chosen to make use of our time to do our part to contribute to the research world. This book provides us with information from South East Asia and India during the COVID-19 pandemic outbreak. How the COVID-19 has infected countries like India, Indonesia, Malaysia, Thailand, and The Philippines. This book has given opportunities to researchers from those countries to contribute their research. It represents a collaboration between researchers from different fields and also from different countries. We collected the information and did our researches regarding the COVID-19 effects to the society, education, economy, information, and technology and also provide some insights about COVID-19 from the medical perspectives.

The aim of this book, therefore, is to share information and scientific evidence and to provide an overview of the topic. This book covers general condition of COVID-19, Health State, Social Condition, Education, and Economy during COVID-19 pandemic, as well as Science and Information Technology in Handling COVID-19.

ABSTRACT

A new epidemic emerged as severe acute respiratory syndrome corona virus (SARS-CoV-2) intensely shook the world. The disease is caused by the infection from this deadly virus, known as COVID-19. The number of cases infected by this virus are increasing day by day. Despite all the control measures taken by all healthcare authorities, the number of death toll is not halting. The crown-shaped RNA virus is reported to be transmitted from animal to human and human to human within 14 days of incubation period. The clinical manifestation of the disease ranges from mild symptoms, including fever, dry cough with sore throat, nasal congestion leading to difficulties in breathing, severe continuous headache, unbearable pain in muscle, as well severe respiratory failure and septic shock. Most of the deaths are observed in old patients or in those with comorbidities. Healthcare regulatory authorities including World Health Organization (WHO) and national Center for Drug Control (CDC) are closely monitoring the situation and are continuously giving the necessary guidelines to avoid further transmission of COVID-19.

1. INTRODUCTION

Combating viral diseases has always been a serious challenge for health authorities throughout the world (Mulyanti, Purnama and Parwinanto 2020). In last two decades, the world has already been threatened by two highly infectious viruses including severe acute respiratory syndrome coronavirus (SARS-CoV), H1N1 influenza and Middle East respiratory syndrome coronavirus (MERS-CoV). The world has not forgotten the damage caused by two of the members of coronavirus family, a novel virus SARS-CoV-2 from the same family has emerged as a biological disaster to mankind.

The second SARS-CoV (known as SARS-CoV-2) infection was first reported in Wuhan, China on 31 December 2019, and the related literature henceforth published can help tracing the origin of the symptomatic individuals back to the early December 2019 (Anggraeni et al., 2020). This virus affects the lower respiratory tract and has some of the symptoms related to pneumonia. Due to unidentifiable etiology of this virus, it was classified as “pneumonia of unknown etiology.”

On February 11, 2020, the WHO named the disease as “COVID-19,” an acronym of “coronavirus disease 2019” (Razon 2020). The earlier infections caused by SARS-CoV that began in China has caused more than 800 casualties with infection spreading to two dozen states, and MERS-CoV that began in Saudi Arabia was equally threatening.

This new virus has been reported as more contagious and having a higher human to human transmission potential. On February 26, 2020, as the first SARS-CoV-2 positive case was reported in United States without having a travel history to China. SARS-CoV-2 is a member of family of single-stranded RNA viruses (+ssRNA) that can infect multiple animal species, especially mammals (Perlman and Netland 2009). Although mechanism of infection is not completely understood, the illness can range from mild common cold to more serious respiratory depression. Origin of coronavirus is linked to bats, Himalayan palm civet, and dromedary camel. Scientists around the world are working day and night to gather the information on the transmission, virus-host interaction, diagnosis, spectrum of disease, and prevention strategies.

2. CAUSE FOR CORONAVIRUS

SARS-CoV-2, like other members of the family, has a crown-like appearance which is due to the presence of spiked glycoproteins on the outer surface. *Coronam* is the Latin term for crown. It is classified under *Coronaviridae* family, *Orthocoronavirinae* sub-family and order *Nidovirales*. Table 1. lists different types of Coronaviruses with their probable hosts (Schoeman and Fielding 2020), (Wang et al., 2020).

HCoV-OC43, and HCoV-HKU1 (betaCoVs of the A lineage); HCoV-229E, and HCoV-NL63 (alphaCoVs) are common human coronaviruses with a viral lineage, and they are potential to infect an individual, causing common cold and self-limiting upper respiratory infections especially in people with a weak immune system (Chan et al., 2013) (Chen, Liu, and Guo 2020). SARS-CoV, SARS-CoV-2, and MERS-CoV are other human betaCoVs with B and C viral lineage have the potential and one of the root causes of severe respiratory and extra-respiratory dysfunctions (Table 1). Multiple reported documents have shown high rates

of deaths up to 10-35%. Although SARS-CoV-2 has a lower mortality rate, which is around 2.3%, the reproduction number is higher than SARS-CoV and MERS (Petrosillo et al., 2020).

Table 1. Types of coronaviruses and their respective hosts

Types	Species of Coronaviruses
Type 1 Alpha Coronavirus	Transmissible gastroenteritis coronavirus (TGEV)
	Canine coronavirus (CCoV)
	Porcine respiratory coronavirus (PRCoV)
	Feline coronavirus (FeCoV)
	Porcine epidemic diarrhea coronavirus (PEDV)
	Human coronavirus 229E (HCoV-229E)
Type 2 Beta Coronavirus	Human coronavirus NL63 (HCoV-NL63)
	Bat coronavirus (BCoV)
	Porcine hemagglutinating encephalomyelitis virus (HEV)
	Murine hepatitis virus (MHV)
	Human coronavirus 4408 (HVoV-4408)
	Human coronavirus OC43 (HVoV-OC43)
	Human coronavirus HKU1 (HVoV-HKU1)
	Severe acute respiratory syndrome coronavirus (SARS-CoV)
Type 3 Gamma Coronavirus	Middle Eastern respiratory syndrome coronavirus (MERS-CoV)
	Avian infectious bronchitis virus (IBV)
Type 4 Delta Coronavirus	Turkey coronavirus (TCoV)
	Bulbul coronavirus HKU11
	Thrush coronavirus HKU12
	Munia coronavirus HKU13

SARS-CoV-2 is a round or elliptic shaped virus with an approximately 60-140 nm in diameter. It is sensitive to heat and UV rays. It can be made inert with the use of lipid-dissolving solvents, which includes commonly used ethanol, isopropanol, chloroform, and chlorhexidine. It has around 80% genetic similarity with human SARS-CoV, making it named as SARS-CoV-2 (Chan et al., 2020). It has a single stranded RNA containing 29891 nucleotides, which encodes for 9860 amino acids.

3. TRANSMISSION OF THE DISEASE

The first case of COVID-19 is linked to Seafood Wholesale Market of Wuhan, China. The transmission of virus has been reported to be from the droplets released from the infected person, which is similar to other viruses attacking the respiratory organs such as the rhinovirus and the influenza. The transmission has been thought to be from symptomatic as well as asymptomatic patients. Reports showed that the infection spreads because of close contact with the infected people. The incubation time of this virus is expected to be 3 to 7 days and can go up to 14 days (Li et al., 2020), (Bauch et al., 2005).

4. EPIDEMIOLOGY

WHO (March 03, 10.00 am CET) reported 87,137 confirmed cases in worldwide. Out of which 2977 cases (3.42%) have been found to be deceased. Nearly 92% (79,968 cases) of the total confirmed cases, and 2,873 cases (96.5%) resulted deaths in China. Outside of the People's Republic of China in March 2020, there are approximately 7,169 reported cases, spanning 59 countries which includes the Republic of Korea with 3,736 cases followed by Italy (1,128), international conveyance (Diamond Princess, 705 cases), the Islamic Republic of Iran (593), Japan (239), Singapore (102), France (100), United States of America (62), Germany (57), Kuwait (45), Spain (45), Thailand (42), Bahrain (40), Australia (25), Malaysia (24), United Kingdom (23), Canada (19), United Arab Emirates (19), Switzerland (18), Viet Nam (16), Norway (15), Iraq (13), Sweden (13), Austria (10), Croatia (7), Israel (7), Netherlands (7), Oman (6), Pakistan (4), Azerbaijan (3), Denmark (3), Georgia (3), Greece (3), India (3), Philippines (3), Romania (3). Moreover, two lawsuits were recorded in Brazil, Finland, Lebanon, Mexico, the Russian Federation, and a single event each in Afghanistan, Algeria, Belarus, Belgium, Cambodia, Ecuador, Egypt, Estonia, Ireland, Lithuania, Monaco, Nepal, New Zealand, Nigeria, North Macedonia, Qatar, San Marino, and Sri Lanka.

In India, the death was reported in a 76-year-old male from Karnataka and 68-year-old female from Delhi, and 63-year old man from Maharashtra. All three with co-morbidities (WHO 2020). Data showed correlation of Age and % Case Fatality Rate in China (Table 2) (The Novel Coronavirus Pneumonia Emergency Response Epidemiology Team 2020).

Table 2. Percentage of fatality rates for different age groups

Age (in years)	% Case Fatality Rate
10 to 19	0.2
20 to 29	0.2
30 to 39	0.2
40 to 49	0.4
50 to 59	1.3
60 to 69	3.6
70 to 79	8
80 and above	14.8

Both South Korea and Italy have high number of patients positively diagnosed with COVID-19 but in Italy the percentage fatality rate is higher as 90% of deaths occur in those 70 years old or older. On contrary, in South Korea the percentage fatality rate is significantly low as most of the positively diagnosed population is young (less than 40 years old). The morbidity rates are higher in men as compared to women (Sepkowitz 2020). Although WHO have stated that people irrespective of any certain age-groups can be potentially infected by new corona virus (2019-nCoV), certain population is more vulnerable, which include (WHO 2020):

- a. Elderly people over 65 years old
- b. Healthcare workers including the doctors, nurses and other staffs
- c. People with following medical health conditions:
 1. Asthmatic or people suffering from any kind of chronic lung disease

2. People with artery blockage conditions and weaker heart
 3. Individuals with high blood glucose levels, otherwise known as diabetic
 4. People with neurological conditions and weaker ability to cough
 5. Individuals going through chemotherapy sessions for the treatment of cancer (currently or in recent past)
 6. Individuals suffering from chronic kidney disease requiring dialysis
 7. Individuals with infections in liver
 8. Individuals with lack of spleen
 9. Extremely obese individuals with BMI > 40.
- d. People who are pregnant* (CDC 2020). Present data shows that there is no transmission of COVID-19 from maternal-fetal (Stower 2020). No maternal morbidity has been observed so far (Mullins et al., 2020).

5. MANAGEMENT OF COVID-19

Although repurposing of several drugs is being done along with the screening of herbal remedies, still health regulatory is continuously advising to take necessary precautions. These preventive steps help to reduce the risk factor, including:

- a. Remaining update with the latest information on COVID-19 available on WHO website or nation and local public health agency.
- b. Maintaining hygiene is an utmost priority. This includes washing or sanitizing hands after regular interval of time.
- c. Maintaining social distancing i.e., at least distance of 1 meter between two persons.
- d. Avoiding in touching the face especially eyes, mouth, and nose.
- e. Wearing a mask at public places.
- f. Practicing good respiratory hygiene by covering the mouth while sneezing or coughing with an elbow.
- g. Seeking medical health when symptoms arise. Not following the practice of self-medication.
- h. Avoiding spreading false claims which comes without strong justifications.
- i. Avoiding public gatherings.

CONCLUSION

It is not the first time that the world has faced an epidemic, but this is certainly one of the most threatening phenomena, at least one in past 100 years. It took few weeks to rise from regional crisis to global threat. To reduce the jeopardy caused by COVID-19, WHO, CDCs, and other organizations are working together to make stringent policies and guidelines to curb the virus transmission.

Chapter 420

THE COVID-19 PANDEMIC IN INDONESIA

Andika Chandra Putra*

Department of Pulmonology and Respiratory Medicine,
Faculty of Medicine, Universitas Indonesia;
National Respiratory Referral Persahabatan Hospital, Indonesia

ABSTRACT

Since the first case of coronavirus disease 2019 (COVID-19) was reported in Wuhan, China, as of 12 June 2020, the total number of confirmed cases of COVID-19 was 7,648,823 cases in 215 countries and regions. In Indonesia, the first confirmed case was reported on 2 March 2020, and since then, the number of cases is rising exponentially on a daily basis. As the largest country in South East Asia, Indonesia is the second-largest number of confirmed cases in South East Asia (36,406 cases) after Singapore (39,850 cases). This situation brings Indonesia like other Asian countries into a catastrophe condition. This report described epidemiologic and clinical features, as well as the management of COVID-19 patients in Indonesia.

Keywords: COVID-19, pandemic, Indonesia

1. INTRODUCTION

Since 31 December 2019, coronavirus disease or known as COVID-19 was firstly found in Wuhan, China. It has spread all over the world causing the pandemic (Mulyanti, Purnama, and Parwinanto 2020; Anggraeni et al., 2020; Razon 2020). This virus was previously named 2019 novel Coronaviruses or known as 2019-nCoV, but then World Health Organization (WHO) changed its name into COVID-19 on 11 February 2020. COVID-19 is a severe acute respiratory syndrome caused by SARS-CoV2, a new virus that thought of as zoonotic and mutated so that it can infect human (Sun et al., 2020). It has the closest similarity to

* Corresponding Author's Email: andika_cp@staff.ui.ac.id.

coronaviruses found in bat, so it is thought to be the primary source. SARS-CoV-2 belongs to betacoronavirus, the same subgenus as Severe Acute Respiratory Syndrome (SARS), and Middle East Respiratory Syndrome (MERS). WHO declared COVID-19 as a Public Health Emergency of International Concern on 30 January 2020, and declared the pandemic on 11 March 2020 (WHO 2020). The first case in Indonesia was on 2 March 2020, and since then, the cases increase exponentially (Indonesia. Kementerian Kesehatan Republik Indonesia 2020).

2. EPIDEMIOLOGY

COVID-19 has a higher rate transmission compared to SARS and MERS. Its basic reproductive number is 2-3, which means one patient can transmit to 2-3 other people. COVID-19 transmission is five times at the early phase. A study in China showed that at an early phase, many patients transmitted a large amount of virus, while the conditions were asymptomatic or mild pneumonia. This caused the virus spread more easily (Wang et al., 2020; Zhou et al. 2020).

COVID-19 is linked to wild animal market in Wuhan, China, pangolins, and snakes. They are linked as the intermediate host. COVID-19 has the closest similarity to coronaviruses found in bat, so it is thought to be the primary source (Sun et al., 2020; Wang et al., 2020; CDC 2020). In China, the majority of patients was men with a median age of 56 years, shown by the fact that patients who need Intensive Care Unit (ICU) were 26% (Zhou et.al., 2020). According to other reports in the US, a total patient reaches 5,700 cases, in which 60.30% of them were male and 39.70% were female. Patients with comorbidities are more vulnerable to get COVID-19. The most common comorbidities were hypertension (55.60%), obesity (41.70%), and diabetes (41.70%). Other conditions were cancer (6%), asthma (9%), chronic obstructive disease (5.40%), history of transplant (1%), chronic kidney disease (5%), and others. Patients with no comorbid reach 6.10%, with one comorbid 6.30%, and more than 1 comorbid were 88%. Patients come into emergency with fever (30.70%), shortness of breath (17.30%), and 27.80% of them received oxygenation. Patients who treated in ICU were 14.20%, and 12.20% received invasive mechanical ventilation, and 3.20% receive kidney replacement therapy (WHO 2020).

Until April 2020, WHO reported 3,090,445 positive cases and 217,669 deaths globally. It has spread in all the continents, except Antarctica (WHO 2020). The case for fatality rate among diagnosed cases is about 2-3%, but it varies by countries (Oke and Heneghan 2020). Chinese Center for Disease Control has reported mortality rate of about 3.46%, which is lower than SARS (9.60%) and MERS (34.50%) (Wu, Leung, and Leung 2020). However, the true mortality rate cannot be ascertained because the total positive cases are still unknown. Furthermore, the average incubation day is about 6.40 days but it varies between 0 and 24 days (Wang et al., 2020).

In Indonesia, since the first announced case on 2 March until April 2020, there are 9,771 positive cases and 784 deaths. COVID-19 has been reported in all 34 provinces but it varies depending on demographic and density (Indonesia. Kementerian Kesehatan Republik Indonesia 2020). The highest rate is found in Jakarta (the highest population density), in which mid-May 2020, it has 34.40% of the cases in Indonesia (Indonesia. Dinas Kesehatan

DKI Jakarta 2020). Based on the latest data from the COVID-19 task force of the Indonesian government, the susceptible sex was male with a mortality increase in age group ≥ 60 years old. SARS-CoV-2 is also more likely to infect people with chronic comorbidities such as hypertension (55.6%), diabetes (35.2%), cardiovascular disease (20.7%), chronic obstructive pulmonary diseases (COPD) (12.6%) and other respiratory problem (5.6%). Among them, the highest proportion for mortality was COVID-19 with hypertension (14.6%) (Indonesia. Kementerian Kesehatan Republik Indonesia 2020). Among 34 provinces in Indonesia (on 12 June 2020) the capital city of Jakarta and the second-largest city of Surabaya are the higher proportion for COVID-19 patients (Figure 1).

Figure 1. Map of the COVID-19 spread in Indonesia. Size of red circle related with proportion of COVID-19 positive cases. (Source from <https://covid19.go.id/peta-sebaran>).

3. CLINICAL MANIFESTATIONS

The clinical manifestations vary from asymptomatic to severe conditions such as respiratory distress syndrome, septic condition, or multiple organ dysfunction. Chinese Center Disease Control and Prevention (CDC) divided into mild pneumonia, severe, and critical disease. About 1% of positive cases did not have any symptoms. 81% of patients with positive cases are mild or non-pneumonia. Severe disease is defined by respiratory rate ≥ 30 times/minutes, oxygen saturation $\leq 93\%$, $\text{PaO}_2/\text{FiO}_2$, and percentage of oxygen supplied < 300 , lung infiltrate in radiograph $> 50\%$ in 24 to 48 hours. The severe disease occurred in 14% cases and the critical disease occurred in 5% cases is patient with respiratory failure, septic shock, and/or multiple organ dysfunction syndromes (MODS).

- a. Moderate pneumonia. Usually patients come with dyspnea and dry cough but without any sign of severe disease
- b. Severe disease. Patients come with fever and sign of severe dyspnea, saturation $< 90\%$, and respiratory rate $> 30\text{x/minutes}$. But in severe disease, the fever could be absent or slightly increased.

- c. Acute Respiratory Distress Syndrome (ARDS). Patients with respiratory failure are divided into (i) Mild ($\text{PaO}_2/\text{FiO}_2$ between 201-300 mmHg. Patients with no ventilator or non-invasive ventilation by Positive end-expiratory pressure (PEEP) or continuous positive airway pressure (CPAP) ≥ 5 cmH₂O; (ii) Moderate ($\text{PaO}_2/\text{FiO}_2$ 101-200 mmHg), and (iii) Severe ($\text{PaO}_2/\text{FiO}_2 \leq 100$ mmHg). Chest radiograph with bilateral opacities not followed by effusions, lung collapses, or lobar also suggested ARDS.
- d. Septic. Sign of shock includes dyspnea, hypoxemia, hypotension, tachycardia, prolonged capillary refill, hyperthermia or hypothermia, and sign of multi organ dysfunction such as oliguria (decreased kidney function), altered mental status, coagulopathy, hyperbilirubinemia, acidosis, high lactate and others. MODS can be evaluated by sequential organ failure assessment (SOFA) which can predict mortality score on ICU based on clinical and lab data.

4. MANAGEMENT OF COVID-19 IN INDONESIA

During the COVID-19 pandemic several specialty societies have published treatment guidance and management related to COVID-19, which is divided into two factors: non pharmacology treatment and pharmacology treatment.

Non pharmacology treatment is explained as

1. Patient should use face mask to reduce the aerosol spread to healthcare and place patient in isolation room with negative pressure (Centers for Diseases Control and Prevention 2020).
2. Oxygenation and ventilation (WHO 2020), (National Institutes of Health 2020).
 - a. Use oxygen when saturation falls below 90-92% (Alhazzani et al., 2020)
 - b. Use nasal cannula 5 lpm or reservoir bag 10-15 lpm with initial target saturation more than 94% (Alhazzani et al., 2020)
 - If the patient is stable, target saturation more than 90% in nonpregnant adults, and 92% in pregnant patients.
 - Saturation target in children is 90% or higher, for children who need urgent resuscitation (apnea or obstructed, distress respiratory syndrome, central cyanosis, shock, seizures, or coma) SpO_2 minimal 94% or higher
 - c. High-flow nasal oxygen or Non-invasive ventilation has been used to achieve adequate oxygenation (Murthy, Gomersall and Fowler 2020).
 - High flow nasal oxygen is recommended for patients with hypoxemic respiratory failure despite using conventional oxygen therapy. There is evidence that this can reduce the need for intubation and mechanical ventilation (Murthy, Gomersall and Fowler 2020; Huang et.al 2020). However, using this technique can result in higher risk of aerosolization virus and still need emergent intubation if the saturation drops suddenly which can risk providers and put patients in more dangerous condition.
 - d. Mechanical ventilation is an option for patient with less saturation who received less invasive measures or patient that cannot maintain breath.

- Tidal volume settings around 4-8 ml/kg (predicted body weight) and inspiratory pressure < 30 cmH₂O.
 - Set tidal volume for children 5-8 ml/kg (predicted body weight) for preserved lung compliance and inspiratory pressure < 28 cmH₂O.
 - PEEP recommended for patient who develop respiratory distress syndrome with higher pressure (>10 cmH₂O) better than lower pressure (Alhazzani 2020; Huang et.al 2020).
 - Patient with moderate to severe respiratory distress syndrome recommend with prone position in 12-18 hours per day, and for pregnant patient in lateral decubitus.
- e. Extracorporeal membrane oxygenation also can be used for severely ill patients if expertise and resources are available (Huang et.al 2020).
3. Fluid therapy
- a. Do not give overhydration because it can precipitate respiratory distress syndrome.
- b. Patient with shock:
- Crystalloids is recommended (balanced more preferred, example: ringer lactate solution) than colloid fluids such as hydroxyethyl starches, gelatin or albumin for patient critically ill with COVID-19 (Huang et.al 2020).
 - Administer within 15-30 minutes 250-500 ml fluid, with target mean arterial pressure (MAP) 60-65 mmHg for adults' patient.
 - For children administered 10-20 cc/kg bolus within 30 minutes.
 - If there are signs of overhydration or no response then discontinue or reduce the fluid.
 - After initial bolus check the clinical signs (CRT, heart rate, the tactile temperature of extremities, palpable pulse), urinary output (0,5 ml/kg/hour in adult and 1 ml/kg/hour in children), and hemodynamic (MAP > 65 mmHg in adults). If the response is good then titrate continues the fluid (Alhazzani 2020).

Pharmacology treatment is explained in the following. COVID-19 patients are divided into asymptomatic, mild, moderate, and severe pneumonia. They are treated according to their conditions. (Protokol Tatalaksana COVID-19 2020).

1. Asymptomatic:
 - a. Self-isolation at home for 14 days.
 - b. Education for patients (for example: given a leaflet to take home).
 - c. Vitamin C 3x500 mg (for 14 days).
 - d. Check the temperature twice a day, every morning and night.
 - e. Surveillance by medical center officer by phone.
 - f. Control in medical center after 14 days surveillance.
2. Mild symptoms
 - a. Self-isolation at home for 14 days.
 - b. Education for patients (for example: given a leaflet to take home).

- c. Vitamin C 3x500 mg (for 14 days).
 - d. Chloroquine 2x 500 mg (for 5 days) or hydroxychloroquine 1x400 mg for 5 days.
 - e. Azithromycin 1x 500 mg (for 3 days).
 - f. Symptomatic therapy (for example: paracetamol for fever)
 - g. Antiviral drug if needed, oseltamivir 2x75 mg or favipiravir 2x .600 mg for 5 days.
 - h. Control in medical center after 14 days surveillance.
3. Moderate
- a. Refer to hospital or emergency hospital.
 - b. Isolation in hospital for 14 days.
 - c. Intravena vitamin C.
 - d. Chloroquine 2x 500 mg (for 5 days) or hydroxychloroquine 1x400 mg for 5 days.
 - e. Azithromycin 1x 500 mg (for 3 days).
 - f. Antiviral drug if needed, oseltamivir 2x 75 mg (for 5 days) or favipiravir loading dose 2x1600 mg for day 1 and then continue with 2x600 mg (day 2-5).
4. Severe
- a. Refer to hospital with facility for COVID-19
 - b. Regimen for COVID-19:
 - Chloroquine 2x500 mg (day 1-3) and continue with 2x250 mg (day 4-19) or hydroxychloroquine 1x400 mg (day 1-5).
 - Azithromycin 1x500 mg (for 3 days).
 - Antiviral drug: oseltamivir 2x75 mg or favipiravir loading dose 2x1600 mg for day 1 and continue with 2x600 mg (day 2-5).
 - Intravenous drip of vitamin C 200-400 mg in NaCl 0,9% 100 cc.
 - a. Supportive therapy (example paracetamol for fever).
 - b. Comorbid therapy (if present).
 - c. Strictly monitor the patient to prevent respiratory failure.

There are no specific drugs approved for the treatment of COVID-19, but there are some drugs being used under clinical trial and compassionate use protocol based on in vitro study:

1. Remdesivir is antiviral therapy recommended for COVID-19 in severe condition ($\text{SpO}_2 \leq 94\%$ ambient air, need supplemental oxygen, mechanical ventilation, or extracorporeal membrane oxygenation). Although this drug has not been approved by the Food and Drug Administration (FDA). It is issued by the FDA for emergency use as IV remdesivir to treat the severe conditions. According to one placebo-controlled randomized trial, the use of remdesivir is significant in improving recovery time yet does not do any differences for mortality (Gilead 2020). However, remdesivir is not recommended for mild to moderate COVID-19 patients outside the setting of the clinical trial.
2. Chloroquine and hydroxychloroquine have been used in some countries, but the guideline does not recommend high dose chloroquine (2x600 mg for 10 days) because of higher serious effect than the lower dose. It is associated with prolonged QT and risk of arrhythmia (Simpson, Kovacs and Stecker 2020). They can be combined with azithromycin in some protocols, but this also can increase the risk of

arrythmia. Infectious Diseases Society of America recommends using this combination only for the clinical trial. NIH guidelines noted when using this combination, patients must be monitored to see the side effects (Clinical Pharmacology 2020).

3. Lopinavir-ritonavir is currently being used to treat HIV. It was used for treating COVID-19 patients but the results are not good.
 - a. A study comparing lopinavir-ritonavir with standard treatment shows no difference between improvement time or mortality in 28 days (Cao et al., 2020).
 - b. NIH does not recommend using this for treating COVID-19 patients.
4. Immunomodulator is expected to reduce cytokine storm which is estimated to be a factor contributing to respiratory distress syndrome in COVID-19 patients (example: tocilizumab or sarilumab are monoclonal antibodies against interleukin-6).
 - a. Convalescent plasma is still uncertain in safety and efficacy for treating COVID-19.
 - b. Recently the panel recommends the use of antithrombotic agents to prevent thromboembolic event in COVID-19 patients because COVID-19 has been associated with proinflammation and thrombotic state, increasing fibrin and d-dimers (Han et al., 2020). But the patient who gets antithrombotic drugs should be monitored and evaluated carefully, so this prevention can only be given to inpatients. outpatients are not allowed to get tested hematology and get prophylaxis except with underlying conditions. This reduces mortality for inpatients with COVID-19.
 - c. COVID-19 patients with suspected thromboembolism should get anticoagulant therapy with therapeutic doses like the standard dose for patients without COVID-19. Patient with extracorporeal membrane or kidney replacement therapy or thrombosis in catheters or extracorporeal filters should get anticoagulant therapy like the standard care for patients without COVID-19.
 - d. Low molecular weight heparin or unfractionated heparin is preferred for critically ill COVID-19 patients because of their short-lived duration (American Society of Hematology 2020).
5. If the patient falls into septic shock condition, the panel recommends fluid administration first and if the condition persists, adding vasopressin is more recommended (Alhazzani et al., 2020; Murthy, Gomersall and Fowler 2020; Huang et al., 2020).
6. Treatment is started with norepinephrine as the first line. Epinephrine or vasopressin as the second line if norepinephrine is unavailable. The target of mean arterial pressure is 60-65 mmHg.
 - a. If the patient is not responding to the usual dose of norepinephrine, adding vasopressin is more recommended than titrating norepinephrine.
 - b. If the patient is not responding to norepinephrine and has cardiac dysfunction, adding dobutamine is more recommended than titrating norepinephrine.
 - c. Epinephrine is recommended for children and norepinephrine is the second line.

Jawa Barat, Indonesia

ABSTRACT

As the world is facing a new threat through virus which was found in early December 2019 in Wuhan, China, the changes are happening rapidly. On 2 March 2020, Indonesian government officially announced that the outbreak had finally reached Indonesia. This study conducted to examine and analyze the COVID-19 pandemic outbreak in Indonesia. The main focus of this study was to investigate the challenges Indonesia encountered and how we combat it. Using the existing and evolving information to provide comprehensive picture of the society. The data was taken using the existing data from the current researches on COVID-19 and the reliable mass media. Our research found three major challenges we encountered namely the physical distancing policy, the increasing of the fake news and messages spreading, rising number of unemployment, which eventually bring new changes in our society. The challenges have made us rethinking about our cultural greeting, our news consumption, and its spreading. Also, it made us thinking creatively to change the way we generate our income. On the other hand, it has been a 'blessing in disguise' where the '*gotong royong*' as our cultural heritage has encouraged us to collaborate to help each other, and it has definitely created an opportunity for nature to reclaim itself, and lastly it also lowers the crime rate.

1. INTRODUCTION

In December 2019, when we read the news about the coronavirus disease 2019 (COVID-19) which had emerged in Wuhan province, China, we did not think that the epidemic would cause global shock. The coronavirus is a type of virus that comes from animals. This virus has a very small size and can infect the human body (Maryanti et al. 2020a). The COVID-19 virus is transmitted through droplets, either directly or indirectly. Viruses enter the human body through the nose or mouth. As the death tolls kept increasing, on 30 January 2020, the World Health Organization (WHO) declared it as a Public Health Emergency of International Concern (Anggraeni et al. 2020). The common signs and symptoms of COVID-19 infection include symptoms of acute respiratory disorders such as fever, coughing, and shortness of breath. In severe cases, COVID-19 can cause pneumonia, acute respiratory syndrome, kidney failure, and even death (Tosepu et al. 2020). However, some patients have not shown those symptoms prior to the test. Currently, there has not been any clinical treatments or prevention strategies available for any human coronavirus (Cui, Li and Shi 2019). Even so, there are some simple steps that can be taken in an effort to prevent contracting the COVID-19 virus. We can prevent this virus transmission in several ways by maintaining physical distance (maintaining a minimum distance of 1 meter from other people), using a mask when we leave the house, diligently washing hands with soap, applying hand sanitizer, body booster, be immune to consuming vitamins and a balanced diet, avoid contact with patients, maintain cleanliness, cover mouth and nose when sneezing and coughing, and do not touch nose and mouth before washing hands (Maryanti et al. 2020b).

Elderly patients are having high mortality rates from COVID-19 infection compared to younger patients (Lake 2020). They have weak immune system. Most human coronaviruses are transmitted mainly by the respiratory route or via contact with infected secretions (Chatterjee 2020).

The lock-down in Wuhan has increased the apprehension including the Indonesian citizens who were staying there (Ana 2020). They requested the Indonesian government to evacuate them. As a result, on 30 January 2020, Indonesian government evacuated 238 Indonesian citizens from Wuhan and later quarantined them for 14 days in Natuna Regency, Riau Islands. Two weeks after the quarantine on 15 February 2020, Indonesian Ministry of Health announced to public that all the 238 citizens were all healthy and could continue doing their daily activities (Garnesia 2020).

Prior to that, Indonesian people had been concerned because cases of COVID-19 had been found in other countries. However, Indonesian government had not taken any prevention action although the WHO had announced it as an international concern. On 2 March 2020, Indonesian government officially announced that the outbreak had finally reached Indonesia after two suspected patients were identified. The number of affected people has been rising since the first announcement. On 28 April 2020, Indonesia reported 9,056 laboratories confirmed COVID-19 cases with 765 deaths (WHO 2020). Although the first case had been found in March 2020, the government was reluctant to enforce a complete nationwide lockdown. However, city mayor of Tegal (a city in Central Java) decided to do local lockdown, regardless of resentment that he might receive from the citizens against his decision (Dzulfaroh and Hardiyanto 2020).

The official announcement affected many sectors. School closures started, most of offices decided to apply work-from-home policy, and religious activities were encouraged to be performed at home. No crowds are allowed. Immediately after the declaration, Indonesian risk communication team COVID-19 or also known as *Gugus Tugas Percepatan Penanganan COVID-19* launched with the goal of communicating relevant information across different target audiences. The objectives of the Task Force on Acceleration of Handling COVID-19 are to improve national resilience in the health sector, to accelerate the handling of COVID-19 through synergy between ministries or institutions and local governments, to enhance anticipation of the escalation developments spread of COVID-19, to develop the synergy of policy making operational, as well as to increase the readiness and proficiency in the prevention, detection and response to COVID-19 (Indonesia. Keppres no.7 tahun 2020).

2. METHOD

The main focus of this study was to investigate the challenges happening during the COVID-19 pandemic outbreak and how we deal with the challenges. All information was obtained from the news mostly covered by *kompas.com*; *tirto.id*; *tempo.com*; and *bbc.indonesia.com*. The data was also taken also from the published papers by typing COVID-19 in Indonesia as well as *virus corona di Indonesia* as the key words search. This study is limited; therefore, several considerations should be taken into account when interpreting the findings.

3. RESULTS AND DISCUSSION

3.1. Indonesia at Glance

Indonesia has 34 provinces, approximately 16,056 islands spreading over with five main islands namely Sumatra, Java, Kalimantan, Sulawesi, and Papua, and 268 million people (Indonesia. Badan Pusat Statistik 2020). Indonesia has been well-known for its diverse culture, which makes it unique. It is a democratic country and has been independent since 17 August 1945. Indonesia adopts the presidential government system. However, the political and administrative system consists of four levels of government such as the central, the provincial level, the district, the urban municipalities, and the villages (Krishnamohan 2016). Thus, the local government has the right to regulate, allocate, and utilize national resource and intergovernmental fiscal relations between central and local government (Hidayat 2017).

3.2. Challenges during COVID-19 Pandemic Outbreak

The consequences of COVID-19 pandemic outbreak have been affected most of our activities. The situation has been challenging for both government and society. According to us, these three topics are the main challenges that Indonesian encountered besides the economy, health, security, information and technology, and other areas. The three challenges

below have been a challenge, however, at the same time enforce us to make a change regardless of our willingness to.

3.3. Physical Distancing

During this COVID-19, local lock down is implemented. We have experienced changes, shifted rapidly after the official announcement. As more information about COVID-19 published on mass media, the more people started to worry because the COVID-19 diseases transfer through droplets (Anggraeni et al. 2020). Maintaining physical distance, improving personal hygiene, including washing hands using soap, and applying hand sanitizers are one of the best preventions that people can take because this virus gives serious threat.

Consequently, people started to panic. Hand sanitizers and masks were two important items that people bought. As a result, the price of these two items rocketed for few weeks after the announcement. Hospitals, clinics and government-mandated community health clinics encountered shortage of Personal Protective Equipment (PPE). This shortage affected the healthcare workers as the frontline because they have to wear PPE in order to prevent the transmission of the virus. However, the shortage has caused a few of the health workers infected.

The physical distancing method has also been affected the way we greet each other. People commonly greet each other in Indonesia by shaking hands. After the COVID-19 case found in Indonesia, it is suggested to avoid this greeting gesture. Shaking hands has been a part of Indonesian culture, however, the virus has forced us to change the greeting into healthier way by clasping hands in front of our chest or simply giving a slight nod.

3.4. Spreading of Fake News and Messages

At the era of social media, misinformation and the spreading of fake news or messages is inevitable. Misinformation and conspiracy theories spread on social media have generated panic and mistrust among the general public, diverted attention away from the outbreak response, and impeded the activities of health-care workers (Cui, Li, and Si 2019). The global pandemic is not only on COVID-19 but also a global epidemic of misinformation—spreading rapidly through social media platforms and other outlets—poses a serious problem for public health (Zarocostas 2020). By 23 March, 2020, there were 44 cases on fake news in Indonesia (Halim and Rastika 2020).

The cases have caused some suspects being charged under the 2016 Electronic Information and Transactions (ITE) Law. The fake news and messages including the death of two volunteers at the Jakarta's makeshift hospital for COVID-19 in the Kemayoran athletes village (Oktaviani 2020), message about prevention of the virus by using UNICEF where one of the statements mentioned that at 26-27°C the coronavirus would die because the viruses cannot live in a hot temperature (Arnani and Wedhaswary 2020).

The spreading of the fake news and messages has made Indonesian police department to conduct round-the-clock cyber patrols, implemented the law enforcement, and continued to educate the public and fight hoaxes with counter-narratives (Antara and Bhwana 2020). It has

also made The Indonesian Ulama Council to urge Muslims not to spread hoaxes and false information regarding the disease, as the council had issued a fatwa on declaring such wrongdoing as *haram* (News Desk The Jakarta Post 2020).

3.5. Unemployment Creates New Ways of Generating Revenue

The COVID-19 pandemic has many major consequences not only for one area but also in whole aspects. It has obviously increased the numbers of unemployed citizens as companies were forced to do massive layoffs. The number is predicted to reach 2.9 to 5.2 million unemployed people if the situation is getting worse (Fauzia and Setiawan 2020). In 2019, there were 5.28% of unemployed people in Indonesia which approximately about 7.05 million. In order to prevent the spread of the virus, government is controlling the transmission by lockdowns and travel bans to “flatten the pandemic curve.” The lockdown has caused financial challenges and uncertainty. The tourism industry in Bali potentially experience the loss for almost 1 trillion IDR each month because most of the tourists coming are from Australia and China (Gamar and Belarminus 2020). The flight blocking has surely been challenging for the people who work in the tourism industry. Needless to say, the massive layoffs have enforced people to think of new ways to support their families during the pandemic. Due to restrictions, lockdown, and the physical distance policy, many have tried to start their small businesses from home by selling some home-made food and offering the service-based jobs such as courier service and in-home haircut service. Restaurants have changed their services, some have changed their system, where they now open online orders, and some shops have conducted the same approaches by encouraging the staff to sell their products online and to get direct contact with their customers.

The changes had been experienced before. We had online applications where we could order food from restaurants; however, there were some restaurants unwilling to apply the same marketing approaches. The pandemic has obviously changed them.

4. A SILVER LINING

Besides the changes aforementioned, there are many other areas that have improved. COVID-19 is a global pandemic and serious threat to human health which halt the economic activities, however it is also considered as a “Blessing in Disguise,” where pollution is reducing and nature is reclaiming itself (Muhammad, Long and Salman 2020). Additionally, the criminal cases have been decreased as reported in Papua during March 2020 the cases have been lower to 277% comparing to crime cases in February 2020 (Aditra and Agriesta 2020).

Ultimately, during this pandemic, we also see how the cultural heritage is emerging. In Wonosari, one of the villages in Yogyakarta, the people collaborated to help families that isolated due to the COVID-19. People provided the food supplies for the families. In Bali, the governor worked with local security officers known as *pecalang* to ensure the lockdown is implemented and people maintain the social distancing. Furthermore, as the health care workers are in the shortage of the PPE, this situation emerged solidarity from some citizens

including celebrities (CNNIndonesia.com) by organizing the funding to buy more PPE and distribute it to hospitals, clinics, and to government-mandated community health clinics in need.

CONCLUSION

COVID-19 has affected most of our activities. It has also caused us to encounter unprecedented time and enforced us to start thinking about the ‘new normal.’ It has caused us to experience new changes at the same time. The challenges have made us rethinking about our cultural greeting, our news consumption and its spreading, as well as also made us thinking creatively to change the way we generate our income. On the other hand, it has been a ‘blessing in disguise’ where the ‘*gotong royong*’ as our cultural heritage has encouraged us to collaborate to help each other, and it has definitely created an opportunity for nature to reclaim itself, and lastly it lowers the crime rate.

ABSTRACT

The COVID-19 outbreak is now a global pandemic as announced by the World Health Organization. Countries like China and Italy are completely locked down in an attempt to control the situation. Countries like India with vast population density have taken multiple major decisions in order to flatten the curve of epidemic outbreak. Multiple states have announced complete lockdown of major cities and even states. The central government has decided to even halt the passenger trains of Indian Railway services. State government have stopped transport services in their respective states. Some cities even have announced curfews in major areas. Private companies have ordered their employees to work from home. Major government services like banks, medical shops, and vegetable shops are permitted to be kept open. The citizens are encouraged to socially distance themselves at the stores for purchasing the daily needed products. Thermal scanners are installed at airports, railway stations, and at the entry gates of government institutions. Multiple isolated wards are being made at major hospitals to provide medical facilities to the affected people.

Keywords: COVID-19, India

1. INTRODUCTION

At the beginning of 2020, a new transmission of a virus is found in more than 200 countries in the world started as we experience the Corona Virus Disease 2019 (COVID-19) pandemic outbreak. On 11 February, 2020, the World Health Organization (WHO) named the disease from the corona virus as “COVID-19,” an acronym of “coronavirus disease 2019” (Razon 2020). The WHO has officially declared the COVID-19 condition to be a global pandemic and the whole world should pay serious attention to it. Thus, all public activities, including educational institutions with a large number of masses, must be halted to reduce the amount of COVID-19 virus transmission and spread.

The deadly virus had infected the humankind after the consumption of some wild animals/birds which was being sold at the Chinese city of Wuhan (Anggraeni et al. 2020). The infected animal/bird from where the virus originated is yet unknown (WHO 2020). From a small province of Wuhan, China, it is now a global epidemic (WHO 2020), (Hamidah, Sriyono and Hudha 2020).

The World Health Organization (WHO) labelled this outbreak as pandemic (a disease that is spreading in multiple countries around the world at the same time). The appearance of severe acute respiratory syndrome coronavirus 2 (SARS-CoV 2) is also known as novel coronavirus (2019-nCoV) or coronavirus disease 2019 (COVID-19) during the end of 2019 year in the Chinese province of Wuhan is now spreading uncontrollably throughout the world.

Apart from China, European countries like Italy, Spain, and UK are facing huge crisis when it comes to provide proper healthcare and medical facilities to the infected citizens and have lost more lives than China did at the similar stage (Financial Times 2020). The outbreak has taken more than 190 countries into its grip till 22 March 2020 with more than 0.33 million people affected worldwide.

‘Quarantine’ is one of the most effective strategy to control the outbreak-like situation of epidemics and communicable disease (Wilder-Smith and Freedman 2020). And, ‘Social distancing’ is a way to reduce contact with the infected to the non-infected individuals. Many countries have failed to contain this deadly virus and now the situation have gone out of control. Developed nations have failed miserably in order to control the outbreak. Scientists and researchers from about 35 leading companies and research institutions are racing hard to come up with vaccines which seem to be a distant dream (Gallagher 2020). Citizens of the countries where the outbreak happened are advised to stay inside and take proper self-care by regularly washing hands with soap and water. The use of sanitizers with more than 50% alcohol content are promoted. People are also advised to use masks and keep social distance from people coughing nearby.

2. AFFECTED COUNTRIES

The major countries which have been an epicenter of this COVID-19 pandemic are China where the outbreak happened, followed by European countries like Italy, France, Spain, Switzerland and the UK, the USA and the Asian nations of South Korea and Iran (Figure 1).

It is also spreading to other countries of the world spanning over 190 countries and territories, in which there are more than 70 countries with over 100 reported cases as on 23 March 2020. From these 70 countries, San Marino has the highest rate of individuals affected per million people which is 5,158 individuals per million, followed by the countries of Iceland (1,665), Andorra (1,462) and Luxembourg (1,275). On the other hand, India has the lowest rate of affected individuals per million people which is about 0.33 individuals per million. Other countries on the list in Figure 1 with lowest per million affected people are Vietnam (1), Indonesia, and Mexico at two people per million. Highest deaths due to the COVID-19 outbreak are reported in Italy which is about 5,476 although it has the world's second-best healthcare facilities. China, from where the deadly coronavirus originated, has reported a total death toll of 3,270 individuals, followed by the countries of Spain (1,813) and Iran (1,685) (Table 1).

Indian Council of Medical Research (ICMR), the apex body of India responsible for formulating, coordinating, and promoting the biomedical research has freshly revised its strategies for the containment of the spread of COVID-19 in order to deliver dependable diagnosis to the individuals suspected of being infected by COVID-19. The government has asked the relevant authorities to check every suspected individual who has international travel history within last two weeks; And, as a precautionary measurement, the government has advised the individuals along with their respective families to strictly follow 14-days quarantine.

Figure 1. Top 10 countries of coronavirus pandemic outbreak.

Furthermore, the government has asked for the COVID-19 test of the individuals suffering from relatable symptoms such as fever, cough, difficulty in breathing, and sore throat. The test should also be done on asymptomatic individuals from day 5 to day 14 if they have come in contact with the infected individuals.

Table 1. Top 50 countries of the world to be affected from to outbreak of COVID-19 pandemic

No	Country	Total Cases	Total Deaths	Total Recovered	Cases per 1 M population	Reported 1 st case

3. INDIAN SCENARIO AND AFFECTED AREAS

Below are scenarios that Indian government conducted:

- ‘Stay in whichever city you are,’ PM Modi urged people; as the number of cases crossed 1700 mark in India (Business Today India 2020).
- Coronavirus cases in India: Several cities across India, including the national capital Delhi and Mumbai were declared to be completely lockdown as cases of COVID-19 infection continued to surge (Chandrashekhkar 2020).
- PM Modi announced a country-wide lockdown for 21 days up to 14 April 2020. For general public (Chandrashekhkar 2020). Inter-state travel was completely banned throughout the country and was allowed only with official government documents under special permissions granted by respective state governments (The Hindu Business Line 2020)
- Only the medical staffers and journalists with proper documentation were being permitted to move out during the lockdown (Bloomberg Quint 2020).

**Table 2. Indian states affected from to outbreak of COVID-19 pandemic
(as on 1 April 2020)**

State/Union Territory	Confirmed	Active	Recovered	Deceased
Maharashtra	325	274	39	12
Kerala	241	215	24	2
Tamil Nadu	124	117	6	1
Delhi	123	115	6	2
Rajasthan	106	103	3	-

Source: <https://www.covid19india.org/>.

- Coronavirus cases in India crossed 1900 on 1 April 2020 with thousands of people testing positive for the infection. Maharashtra and Kerala with 325 and 241 cases respectively were recorded making them worst affecting states of India (India Today Web Desk 2020).
- Followed by the above-mentioned states, southern Indian state of Tamil Nadu had witnessed a rise of 124 corona virus cases, while the national capital Delhi had 123 on-record positive cases.
- Union territories of Jammu and Kashmir, Chandigarh, Ladakh, Andaman and Nicobar Islands and Puducherry were also heavily affected due to the outbreak of the COVID-19 pandemic.

4. STEPS TAKEN BY INDIA TO FLATTEN THE CURVE

India with the world's second highest population is now facing a challenge to secure the lives of its citizens from the deadly virus. If the spread of this COVID-19 pandemic spreads like in the US and the European nations, then the country may witness massive loss of human lives as well as severe economic losses. The PM of India has urged people to stay indoors for the restricting the outspread of this disease. For flattening the curve of the reported cases, 21-day country-wide lockdown is announced from 24 March 2020. During the lockdown, the police forces are deployed to ensure public stays inside their houses. The daily necessities and food items are made available to public via home-delivery service. The medical stores are also been ordered to be opened. Indian railways are closed completely to stop people to travel in masses. The railway coaches are being transformed into healthcare bogies to make medical facilities available to distant places in the country. Indian airline companies too are playing a major role in controlling the spread of virus. Indigo has said that it will be operational on only 60% of its routes while Vistara and GoAir have also announced curtailment of their service to help the government in checking the spread of highly infectious COVID-19 (SNS Web 2020). The curfew has been declared basically to break down the chain of spreading the virus between the infected people and others. As a learning from the mistakes of Italy, UK, France, and Iran to prevent the stage 2 to stage 3. If people of India used to go for a minimum quarantine time, in the 3rd and 4th weeks of the crucial time of spreading the virus, India could save its people.

Apart from the central government, respective state governments played their part to control the situation as well. Delhi CM Arvind Kejriwal has ordered the closure of all shops, malls, and other places that are prone to contagion with exceptions given to pharmacies and grocery stores. Delhi CM Arvind Kejriwal announced to even lockdown the national capital to prevent the outbreak of COVID-19 if the situation worsens.

Establishments in the state not to terminate the services of its employees even if they go on leave in view of the COVID-19 outbreak. It also asked these establishments not to deduct the wages of their employees. In his directive, State Labor commissioner Mahendra Kalyankar said that if any worker goes on leave, he should be deemed to be on duty without consequential deduction in wages for this period (The Economic Times 2020). Furthermore, Bihar shutdowns bus services, restaurants, and banquet halls to prevent the spread of COVID-19. However, home-delivery and take-home services of restaurants will remain functional,

PTI quoted a health department order (Patna 2020). Odisha lockdowns 40% of the state to knockdown COVID-19, including state capital for a week, 5 districts, and 8 major towns. 70% of the total 3,200 foreign returnees belong to these districts. Airport, railways, bus-stand, and essential services were exempted. All service providers, including private sector, engaged in COVID-19 relief services, to be declared Emergency Workers: Naveen Patnaik, Chief Minister of Odisha (Mohanty 2020).

The West Bengal government ordered all restaurants, bars, pubs, nightclubs, amusement parks, museums, and zoos to be shut down as a precautionary measure in wake of the COVID-19 pandemic. It aims to prevent all non-essential social gatherings. The strict action would be taken in case of any violation (Deccan Herald 2020). UP government under CM Yogi Adityanath announced to provide financial help to labor (about Rs. 1,000 per month) for meeting their daily requirements due to non-availability of work (India Today Web Desk 2020).

Kerala government under the leadership of CM P. Vijayan announced Rs. 20,000 as a special economic package, for disbursing two-month of advance payment of pension. Those without any welfare pension will be provided Rs. 1,000 each along with free ration for all. Additionally, Rs 500 for health package also being announced (The New Indian Express 2020). Karnataka CM B. S. Yedurappa has stated to release fund of amount 200 crores to fight against the COVID-19 pandemic outbreak. In addition, foreign returning individuals are being stamped to ensure the complete safety of all the residents of Karnataka, and must be quarantine for 15 days (Pinto 2020).

The ministry of health and family welfare have started training for critical care management at 1,000 places through video conference. Health ministry joint secretary Lav Agarwal told reporters that guidelines for coronavirus tests have been revised, directing that asymptomatic direct, and high-risk contacts of confirmed cases should be tested once between day 5 and day 14 of coming in contact with an infected person.

Some initiatives from other institutes for the control of COVID-19 outbreak are:

1. *Teachers to work from home.* Teachers and non-teaching staff of universities, colleges and schools permitted to work from home: Amit Khare, Secretary, Ministry of Human Resource Development (Hindustan Times 2020).
2. *Using of Hand Sanitizer.* In each and every shopping complex are providing sanitizer to each and every customer during the entry to the shopping mall and the exit of the mall. The ministry has also informed to sanitizer maker/provider to provide hand sanitizer under Rs. 100/- for 200 ml (Niyogy 2020).
3. 111 labs to test COVID-19 across the country will be functional from today to test coronavirus (The Economic Times 2020).
4. All restaurants, pubs, bars to remain shut across the country. The restaurants are being allowed to provide home-delivery facilities of food to ensure no citizen goes hungry in the difficult time (Deccan Herald 2020).

CONCLUSION

The government of India was keeping a watch on the situation around the globe and has made efficient strategies to combat this COVID-19 threat, including lockdown whole country, reduce the prices of sanitizers, give fund, increase the testing of sample, disinfect the suspected areas. The statistics showed that the action taken by Indian government has slowed down the spread of COVID-19 infection. Albeit, the number of cases is rising but the rate is not very high as compared to the other countries. The preparedness of India can be shared with other nations as all other nations have been sharing their strategies, experiences, and precautions to reduce the number of positive cases. This COVID-19 pandemic threat faced by the world could be stated as an unpredictable the third world war.

Universitas Pendidikan Indonesia, Bandung, Indonesia

ABSTRACT

The Coronavirus Disease in December 2019 (COVID-19) pandemic continued to spread to the whole world. On 12 March 2020, President Rodrigo Duterte announced the month-long lockdown of the entire Metro Manila from 15 March to 14 April 2020. Within this period, vehicles traveling include land, air and sea to and from Metro Manila were suspended, followed by social and religious events involving mass gatherings. Conferences, seminars, and related events were also postponed and people were told to stay home. The government was merely following the usual procedure, such as the implementation of thermal screening at airports to detect arrivals with flu. The COVID-19 was not of great importance for most ordinary people in the Philippines, but the lockdown has both the downsides and the upsides. It has affected the economic, social, and psychological aspects. Needless to say, a tragedy or misfortune to a place or individual may be an advantage for others. Therefore, the economic, social, and ecological aspects have been seen as favorable and beneficial opportunity during this lockdown. We have also learned the value of compassion and empathy during this crisis. This COVID-19 prompted the Philippines to unite to resolve the crisis. '*Bayanihan*' value encourages people to fight the negative and undesirable things in the community and finding the opportunity which can be used and developed.

Keywords: Bayanihan, COVID-19 virus, Filipino

1. INTRODUCTION

Since December 2019, an increasing number of cases of novel coronavirus (2019-nCoV)-infected pneumonia (NCIP) have been identified in Wuhan (Li et al., 2020). The outbreak of serious acute respiratory syndrome coronavirus (SARS-CoV-2) has now reached pandemic proportions, affecting more than 100 countries in just weeks (Remuzzi and Remuzzi 2020). On 11 February 2020, WHO announced the name for the coronavirus disease as COVID-19. The virus transmitted between humans via respiratory droplets and also with other possibilities that it can be transmitted through direct or indirect contact with mucous membranes in the eyes, mouth, or nose (Li et al., 2020). This shows the reasons why people are aware of COVID-19 since it can attack several organs in the human body. The impact of COVID-19 is a catastrophe because as of 14 April 2020 it has infected no less than 1.9 million people in the world and kills thousands (Corona 24 news 2020).

However, the COVID-19 was not of great importance for most ordinary people in the Philippines. The news about this virus originated from China can be heard in both local and international television networks. It made us recalled the unpleasant experience as we feared the influenza virus (known as H1N1) in 2009. As we heard the news on TV, airports were fitted with a thermal scanner to identify arriving passengers and were instructed to quarantine as detected (Razon 2020). People traveling from countries with H1N1 cases were also advised to do home quarantine to prevent the virus from spreading. It was a monumental experience yet unpleasant. People who took a flight to Osaka, Japan were out on masks uncomfortably as they disembarked. At that period, most ordinary citizens in the Philippines were not affected by the H1N1 pandemic.

Therefore, for Filipinos the coronavirus was just similar to those previously known viruses and was not of big importance. Additionally, most ordinary people including those educated but without scientific inclination do not know what a virus is. Virus is a borderline between living and non-living things, not capable of reproduction but only do this process utilizing the machineries of a living cell. Virus infections are often experienced by most people regardless of status in life such as viruses that cause chickenpox, mumps, sore eyes, and many other illnesses. Some viral infections last for only a short period of time while others serious might last for a longer period and can have a serious impact on the person such as the poliomyelitis virus and many others. International Health organizations such as the World Health Organization (WHO) is making efforts to stop the spread of these viral infections in some ways such as developing vaccines and ensuring the availability of medicines and antiviral agents.

Consequently, countries are working on giving clear and concise information about the symptoms, the transmission, the preventive measures, and the socioeconomical impacts. The continued spread of the virus is the reason why mass media still disseminate awareness through print, television, and other methods to educate people about the best way to wash hands, the proper strategies to sneeze in public and many other acceptable hygiene practices to avoid the widespread. However, cases of confirmed coronavirus positive continued to rise almost exponentially.

Although the outbreak is likely to have started from a zoonotic transmission event associated with a large seafood market which also traded in live wild animals, it soon became clear that efficient transmission from person to person was also happening (Zhou et al., 2020)

and consequently the discrimination of the Chinese nationals is also occurring. As an example, in the northern part of the Philippines, before a research conference, the Chinese researcher who supposed to be one of the plenary speakers cancelled the agenda for fear of creating panic to the participants. Another case, when Filipinos encountered Chinese-speaking tourists wearing a mask in the plaza and indeed, they refrain from getting near to them. This was the start where the face masks in the drug stores were out of stock and it was very difficult to find one.

Initially, people did not think this virus would have any significant impacts. However, as the number of people infected by COVID-19 was increasing, at the same time, the fear of getting the virus was also increasing. As a result, some students from the Philippine Science High School in Korondal City commented on the slow action the president took. At that time, airport was still remained open and flights from other countries which considered to increase the spread of the virus were still run. As the death toll was rising, the government became more concerned about the issue of coronavirus. On 12 March 2020, President Rodrigo Duterte announced a month-long lockdown of the entire Metro Manila from 15 March to 14 April 2020. Within this period, vehicles traveling include land, air, and sea to and from Metro Manila were suspended, followed by social and religious events involving mass gathering and also conferences, seminars, and related events were postponed. People were told to stay home. President Rodrigo Duterte announced the effect of the lockdown by on 11 March 2020, night live on ABS CBN (US News 2020).

Regardless of the lockdown, the virus continued to spread rapidly and some Filipinos started to fear the virus since death cases were increasing as it continued to spread. People did not think this virus would have any significant impacts in the Philippines. Due to its simple transmission, the spread of the virus is vast and rapid. Most sick people in the Philippines are those with a travel history outside the country and it spreads to other people in the provinces who also have travel history to the capital city. As the lockdown started, intensive distribution of information and ongoing education to the public was also started. People were given information on the “dos” and “don’ts” while fighting on the COVID-19.

This rapid change is not easy for many people. There were some challenges at the initial stage of the lockdown. There was chaos on the checkpoints, and some people could not stand on the situation. All citizen was encouraged to wear masks, did handwashing as often as possible with soap and water, put on hand sanitizers, and maintained social distancing. The change is inevitable and all Filipinos have been affected. Although the infection is not common among economically challenged people but the effect of the lockdown experience by all citizens regardless of the social status.

Therefore, this study aimed to scrutinize the *Bayanihan* values among Filipino because we believe the values encourage people to fight the negative and undesirable things in the community and finding the opportunity which can be used and developed. As much as the COVID-19 has affected the economic, social, and psychological aspects, however, at the same time we have also learned the values of compassion and empathy during this crisis.

2. LOCKDOWN EFFECTS TOWARDS THE LOCAL COMMUNITY

COVID-19 has devastated the income of the people. It affects economic activities, such as disruption in the manufacturing, transport, tourism, and other works sectors, which leads to financial distress among those who are on the status of ‘no job no pay.’ The lockdown as a way of enforcing group quarantine has clearly resulted in both negative and positive issues for the government and people.

2.1. The Negative Impact

The negative aspects could fall into economic, social, and psychological aspects as commonly observed scenario in our place.

2.1.1. *Psychological Effect*

As stated earlier that the number of the death toll during the COVID-19 pandemic has infected the mental stated of the people. People are worried that their family might be the victims of this virus. Due to the increasing fear, the panic buying for masks, rubbing alcohols, and hand sanitizers happened. As a result, these items were out of stocks. This can imply that people buy such products to avoid infection or some could hoard supplies, and eventually sell them for higher price.

Additionally, people who are sick or unwell choose not to visit the hospitals for fear of being infected. Although they have different types of sickness, they are reluctant to go for medication. Besides, the fear of running out of food supplies and money during the lockdown has also contributed to their psychological condition. This fear eventually might contribute to depression that people might encounter during this uncertain time.

2.1.2. *Economic Effect*

COVID-19 has added to the immense economic costs not only for the vulnerable but also for the country as a whole (Mahmud and Minghat 2020). In the Philippines, 50% of the population are poor people (Zoleta 2020). Therefore, it is not easy for the government to solve this issue. The government made a scheme of providing cash amelioration in the amount of Php 5.000 (± 100 USD) to this economically challenged family (Colcol 2020). The Department of Social Welfare and Development (DSWD) was assigned to arrange the distribution. A food package consisting of five kilograms of rice, three packages of instant noodles, and three canned sardines were also distributed. Needless to say, that the most affected people are the poor people who only have a budget for one-day consumption and with the lock down, these groups of people cannot go working. They are also still worried about the insufficient supplies during the lockdown. However, few families have started planting easy to grow vegetables in the prevention of the extended and continued lockdown.

2.1.3. *Social Effect*

As mentioned earlier, vehicles traveling include land, air, and sea to and from Metro Manila were suspended. This has affected the lower-income families the most. So, many people could not go home and could not be with their families during the lockdown. The

COVID-19 crisis has a social dimension (Hasanah et al., 2020, Sangsawang 2020). At the beginning, the upper and middle-income classes are specifically affected as they are the ones who have traveled or are acquainted with others who have traveled (National Economic and Development Authority 2020). Government also told people to maintain social distancing and avoid involving mass gathering including social and religious events and also conferences, seminars, and related events were postponed and people were told to stay home. As a result, academia has to reschedule and reconstruct schedules. Socializing outside the house is forbidden and drinking liquor outside the house is also banned. Unfortunately, healthcare front liners have encountered discrimination due to the fear of them carrying the virus.

2.2. The Positive Impact

Undoubtedly, COVID-19 has disrupted our life. However, a tragedy or misfortune to a place or individuals may be an advantage for others. Currently there are plenty of issues that are positive and helpful to many people during the lockdown.

2.2.1. Ecological Aspect

According to the Philippine Department of Environment and Natural Resources, the air pollution in the capital city, Manila, was remarkably reduced since most people stay at home. The burning of fossil fuels is also decreasing as the streets are mostly silent and we do not have both domestic and international flights. Garbage piles are also reducing as most hotels, restaurants, and tourist destinations are closed. Mother Nature is taking its time to recover.

2.2.2. Social Aspect

The social aspect seems not only having a negative impact but also beneficial effects. During this COVID-19 pandemic outbreak, Filipinos have shown the “*Bayanihan*” culture that we have. *Bayanihan* is also called the ‘community spirit’ where people help out neighbors in order to make the job easier and to ease the burden through collaboration. It is commonly observed during disaster and hardship. Fortunately, it is happening during the COVID-19 pandemic.

Although healthcare workers initially encountered discrimination but realizing the *Bayanihan* value, people stated showing support to them by giving food, water, masks, and other personal protective equipment they need. Some people sing for the healthcare staff and the patients by keeping maintaining the distance, and some send encouragement notes.

Additionally, many families in the Philippines are intact families. The lockdown has given more opportunities for families to devote longer times with their loved ones and do more family bonding activities. This, undoubtedly, has contributed to their immune system as people also promote health practices by taking a balanced diet. People have also learned to affirm their faith and loyalty to God as they show more concern for their fellows. For some Christians, the coronavirus is God’s will to make people repent and make them believe that God is still in control above all.

2.2.3. Economic Aspect

As aforementioned that COVID-19 has affected the economic condition adversely (Dirgantari et al. 2020). However, it has also encouraged people to be creative. Due to the lockdown and the social distancing policy, people are not allowed to go out unless they go by motorcycle. Even so, only one person is allowed on the motorcycle. Therefore, people find it difficult to buy their daily needs. But some people came up with the idea of “mobile market.” Although the price is higher than the market, but online selling has been more popular. For the seller, they get bigger return than usual and for the buyer it is more practical and less risky than sending one member of the family to go out. In addition, the government-owned employees have been given two months of loan deduction from the Government System Insurance Service in order to help them with their needs during the lockdown.

CONCLUSION

COVID-19 is and has seriously destroyed human lives and disrupted economic development in all nations. It gives pain to the families and relatives of the victims. It challenges all the world leaders to find solutions. However, there are also good things that evolved from this pandemic effect. It can give good results and impact to communities and countries. The lockdown in all parts of the Philippines has brought solidarity between family members and people in the society. In times of crisis, the lesson from the current situation is the importance of compassion and empathy. One of the most significant results of this pandemic is its ability to move the people in the Philippines to reinforce the Filipino importance of *bayanihan* or “community spirits” and to combat this pandemic together as one. The whole world will overcome this crisis, together we heal as one.

ABSTRACT

This article analyzed the narratives of patients as one of the most productive methods of psychotherapeutic work with adults, particularly work aimed at the development of man, his manhood. The authors paid special attention to the problems of the metaphors of the signals and triggers a psychological transformation. The aim of the study was to analyze the problems of anticipating and minimizing the stress of changes in the life of a person (patient). The research method was theoretically understanding of the problems of anticipating and minimizing the stress of changes in the life of a person (patient). The main results of the study showed the patient overcame estrangement from himself and the world, liminality. A metaphor in a person's life acts as a signal and a trigger for change: its use, one way or another, reveals zones that are subject to changes and stimulates changes themselves. Metaphors manifest themselves in various archetypal structures and in specific metaphors of role models. They allow you to evaluate the direction of the patient's internal movement towards the realization of a particular motivation, intention, support upward and/or slow down downward intentions, as well as comprehend how the patient perceives external changes, how he experiences stress of changes.

Keywords: narrative psychotherapy, markers of change, stress of change, the archetypes, triggers for change

1. INTRODUCTION

Stress and change are an integral part of the human life. The stresses of change (a concept introduced by M.R. Arpentieva in 2020) can be smoothed out and transformed by anticipating and understanding them. One approach is to study the precursors of change and transformation by analyzing life scenarios and narratives. This moment is especially relevant in working with people mentally and somatically ill, patients (Arpentieva 2015; Arpentieva and Terentiev 2016; Mindell 1997; Minigalieva 1999).

In working with narratives, special attention should be paid to combining diachronic and synchronous analysis: changing patterns of behavior and the essence of participants' actions at different stages of their life paths, in different worlds and times. Particularly great attention in this context should be given to metaphors - denoting worlds and times, as well as - accomplished or emerging transitions between worlds and times. Metaphors act as bright signals and triggers of change. Each metaphor is a germ or designation of intention, which the heroes follow on their way to themselves, to each other and to God, to happiness and the resolution of the crisis.

The purpose of the study was to analyze the problems of anticipating and minimizing the stress of changes in the life of a person (patient). The research method was a theoretical understanding of the problems of anticipating and minimizing the stress of changes in the life of a person (patient).

2. RESULTS AND DISCUSSIONS

2.1. Transderivational Search and Understanding of Changes

On the way to resolution, the patient overcomes estrangement from himself and the world, liminality. He learns to comprehend changes in himself and the world, recognizing their being and the right to change. Recognizing oneself and other patients in a particular narrative, recognizing themselves and each other as heroes of the narrative, their self-understanding and understanding of other people are processes that can be almost parallel. The condition is semantic resonance: in the process of studying a narrative in the inner world of a person, a search for similar content between the composing narrative and his life world takes place. The fragment of the world' image resonates with a fragment of a fairytale world, a semantic (semantic) resonance arises, due to which it is "unpacked", a new one is updated, productive and more accurate understanding of what is happening (Arpentieva and Terentiev 2016; Bazhov 1993; Hilborn 2004, Meadows 1999. "Transderivational search" - the search for correspondence to the current situation of the patient and fragments of the experience of stress of change, given in the form of a metaphor, story/narrative, script (fabulous or relational).

In order to overcome the non-constructive methods of self-defense associated with this process, to make the structure-schemes and processes-strategies for understanding oneself and the world developed during previous professional and general life experiences, a metaphorical language that integrates the value relationship of a person to himself and the world becomes necessary. As well as ways to translate this relationship into real life - in the process of understanding what is happening and communicating with another person. Metaphors eventually become markers and triggers of change: sometimes nothing acts as strongly as a metaphor applied and/or captured by those who communicate. Moreover, her understanding is the deconstruction of the polylogue of “weak” and “strong” voices (Arpentieva 2015; Packard 2001; Pekar 2010; Ufimstev 2009).

Each of the possible strategies of understanding - based on strong and/or weak signals or voices - acts as a set of ways to understand yourself and another person, the world. Generally speaking, markers and triggers of change can be very intense, explicit, related and declared values and goals of the patient and/or his relationship system. Moreover, they are formed in the form of concepts that have more or less fixed social meanings and personal meanings. They can be weak, hidden, including those associated with implicitly existing, but up to a certain point, not manifested system characteristics. They take shape and arise in dialogue with the therapist and other people in the form of metaphors. Their peculiarity lies in the fact that even minimal changes in the parameters lead to disproportionately significant changes in the behavior of the entire system: these supersensitive zones are usually called “chaos boundaries” (Lewin 2000; Prigozhin and Stengers 1986).

2.2. Between Worlds: Transformations at the Border of Spaces and Times

It is difficult to find “pure chaos” in the surrounding world, and just as it is difficult to find the absolute order. Instead of a limited complex adaptive system surrounded by chaos, the researchers have in front of them an unlimited complex heterogeneous and adaptive environment that looks like an endless “patchwork quilt”. There is “relatively pure” chaos as complete uncertainty: the ordering forces here do not act or act differently, including in the direction of increasing chaos. The “boundaries of chaos” can be called the “boundaries of orders”: they are located at the junction of the flaps, at the junctions and interactions of the regions of orderliness and homeostatic stability (Beytson 2000; Packard 2001; Prigozhin and Stengers 1986; Ufimtsev 2009). In these junctions there is a conflict and interaction of two (or more) neighboring orders. The “points” of personal or social reality located in them fall under the conflicting influence of two or several homeostatic systems at the same time. This creates a special “tension” in them comparable to the border transition between two hostile countries. One order is contrary, hostile to the other. Where two orders are in contact, tension arises and close mutual attention develops disproportionate sensitivity even to minor events (“provocations”). Here, nonlinear, recursive characteristics appear, which one of the creators of the theory of complex systems Ed pointed out. Lorentz: their ability to be hypersensitive in certain areas, striving for “strange attractors” instead of “logically explainable” (Hilborn 2004; Lorenz 1995; Prigozhin and Stengers 1986). These zones can be called borderline or shimmering, obeying the described the concept of butterfly effect. The butterfly impact

denotes the property of some chaotic systems: a slight effect on the system can have large and unpredictable consequences elsewhere and at another time.

The general characteristics of the areas of order are: adaptability; sustainability; the desire for expansion as the development of accessible space; susceptibility to phases of the life cycle, the duration of the phases of which varies depending on the scale and content of the structure (Ufimtsev 2009). Usually it including the phases: the phase of the emergence of “key ideas”, the “core”, the rapid development and capture of new areas as a result of adaptation to a wide range of conditions (phase of active expansion), a phase of defense against competing structures and a phase of collision with changing external conditions and decay (Ufimtsev 2009).

Common characteristics of “flickering zones” or “areas of collision of orders” are maladaptation, instability/variability, life cycle instability, and the ability to enhance or weaken the expansion of “zones of order”. In the border zones or “seams” between the “flaps” of social reality, areas of order are actively clashing, and unique properties of “flickering zones” arise. For example, the “hypersensitivity” of cognitive structures to its periphery, the “sensitivity to problems” of this periphery, and, therefore, the entire “flap” — the concepts, concepts, percentages and (re) constructed by them of social phenomena and objects (Bakurova 2015; Ufimtsev 2009; Van Raj 2012).

Metaphors indicate the presence of “flickering zones”. They, like strict concepts, can denote the same fragments of reality - the same “flickering zones”. Moreover, they have different “indicator value”, revealing the meaning of the tension of relations between concepts and concepts in the border zone, the “between” zone. The general signs of “indicator value” and the separation of metaphors are as follows: repeated repetition of a metaphor in various circumstances by different people; the metaphor is not repeated literally, but modified with the preservation of meaning; a metaphor is spread socially (Leskov 1981; Ufimtsev 2009).

However, in addition to the artificial metaphors generated by people, there are also natural metaphors created by a stream of socially significant events and pointing to “flickering zones”, the existence of which is not yet recognized and which manifest themselves as “strange coincidences”. “Irony of fate”, “jokers”, in practice events that are not connected both in space and in time with each other - synchronisms as manifestations of the collective unconscious: the plots of events are metaphorically identical (Hilborn 2004; Howe and Strauss 1997; Jung 1996; Khlebnikova 2013; Meadows 1999; Van Raj 2012; Zinkevich-Evstigneeva 2013). Through synchrony of apparently unrelated events, the collective unconscious “indicates” the appearance of “flickering zones” of social reality in which significant events occur (Frants 1998; Jung 2003).

2.3. Identification of Markers of Change and the Transformation of Reality

At the junction of reality, borderline or “flickering zones” there are points that are most effective and productive from the point of view of understanding the essence of development difficulties and the productive transformation of reality: influences can be produced with more or less purposeful directing of events and facts that have metaphorical significance. To increase the likelihood and intensity of the desired effect of interventions in these zones, one

can resort to methods of increasing their “indicator value”. We can resort to repeated use of a language or event metaphor, its variation while preserving the essence, and widespread use of language - artificial or event - natural metaphors in social space. For example, we can resort to “sowing” as repeated use of event and language metaphors along the “target” “flickering zone”.

D. Meadows, a student of J. Forrester (Forrester et al. 1977; Meadows 1999; Meadows 1999) examines the limits of the cybernetic approach to the study of complex social systems. J. Forrester already in the 60s of the XX century began to model and study complex social systems (“system dynamics” - the study and prediction of complex systems using computer simulation methods based on cybernetic schematizations). He wrote about the presence of “sensitive points” in these systems, which are the preferred targets for interventions in complex systems. These targets allow you to purposefully change the behavior and condition of large and complex systems with minimal loss of strength and means (Forrester et al. 1977). D. Meadows used the term that is used by system analysts - “leverage points”, which can also be translated as “sensitive points” - places in complex systems in which even a small shift can lead to big changes in the whole system. She believed that people often intuitively know where sensitive points are located, but either do not pay attention to it, or try to put pressure on it in a direction that is not productive for the individual or group: errors of intuition arise. Therefore, J. Forrester called these points “counter-intuitive”: everyday life and its intuition suggest incorrect movements, leading to a systemic deterioration of the problem (Forrester et al. 1977; Meadows 1999; Meadows 1999; Sangsawang 2020; Hasanah et al. 2020). In terms of the metacognitive approach, we are talking about the fact that the use of everyday heuristics without reflection of the areas of their application often leads to errors (Arpentieva 2015; Arpentieva and Terentiev 2016; Minigalieva 1999).

In the work of D. Harris and St. Zeisler on weak signals as “signs of big changes” (Harris and Zeisler 2002) disclosed one of the approaches to forecasting, based on the representation of social reality as a complex adaptive system in which the so-called weak signals appear and the development of “weak signal amplifiers” to help understand them. The richest source of weak signals is the periphery of culture: 1) interdisciplinary, inter-traditional; 2) kitsch and simulated, pseudo-art and pseudoscience; 3) extra-traditional, cultural, anti-science and anti-art. That is, rejected and forbidden, unusual and rare, devoid of price - worthless and priceless, and also magical, fabulous, which is why narrative therapy has the most significant psychotherapeutic potential among other types of psychotherapy.

According to the theory of “amplification of weak signals”, a targeted search for weak signals at the boundary of chaos is the first step in their search. The second step is to understand weak signals, which should not be carried out by methods that understand strong trends: statistics and sorting are unproductive here. An intermediate procedure for understanding them is the “weak signal amplifier” - which helps to filter out weak signals from noise by their ability to cause changes in a complex adaptive system (Ufimtsev 2009).

However, the future makes itself felt not in one weak signal, but in their series distributed in various parts of the “flickering zones”. A weak signal, unlike noise, combines (often unusual and incomprehensible) a number of cognitively significant factors that are pointless to “sort through” individually and logically and linearly calculate their potential. Therefore, the “fishing” and the “breadcrumb road” described by E. Mindell are more productive: simply waiting for a “weak signal” without the intention to typologize it and create a space/study of its self-realization space (Mindell 1997). Closest to him is the “integrating impression”

regarding the methods and strategies of understanding. All the “crumbs” of the picture are important. They are all transferred from the “background - periphery” to the “center-figure”. All of them find their gestalt: where the gestalt is destined to be acquired. In addition, in order to use the weak signal amplifier and other techniques for working with metaphors that serve as indicators (markers) of changes, it is necessary to identify the perspective that helps to search for weak signals. If this is impossible, then you just need to adopt the idea of the need to develop “sensitivity to problems/signals”, being in a state of “active listening”, including:

1. The irregularities of the “psychological texture”, errors and holes (gaps) in a complex system and its manifestations;
2. “Information leaks”, blocks - resistances and facades - interaction barriers;
3. Repeating and ignored zones, concepts and concepts;
4. Ordinary and unusual forms and contents of interaction,
5. Discovering both problems and methods of solving problems in the functioning and development of the system.

Instability zones (“flicker zones”) are the boundaries of chaos that arise at the junction of stable zones. At these points, control signals come from a number of stable regions and enter into non-linear interactions, “quasi-chaos”. It is at these points that the system is very sensitive and variable (Ufimtsev 2009). Areas of sustainability are areas of established and self-sustaining collective representations (values) of oneself and the world, unstable areas are areas of “cognitive flicker”, conflict, and the transformation of various meanings. To find weak signals, you need to find significant things/events in the border areas - seams and joints - stable areas that are characterized by unusual and asymmetric, strange coincidences and repetitions.

M. Scheffer et al. also consider the topic of “early warning signals” of critical transitions to models from catastrophe theory: they call the point when the system is between two possible equilibrium states, jumping from one to the other under the action of even minimal influences, a bifurcation point or a phase or critical transition point (Scheffer et al. 2009). In their opinion, there are signs of approaching this point. Decrease in system resistance and its “critical slowdown” - the system is long restored from various fluctuations and perturbations, in contrast to the equilibrium system, which immediately returns to the state of homeostasis and relative isolation).

The critical state of a complex system can be more precisely related to the scale invariance (fractality) of the system structures: when the system structures acquire the property of “scale invariance”, they become self-similar, then the system is in a critical/transition state, and the fact that designated self-similarity and there is a “weak signal.” A fractal is a typically recursive model, each part of which repeats in its development the development of the entire model as a whole and is reproduced at various scales without major changes. The erosion of the characteristic spatial and temporal relationships in the system and the general drop in energy are common signals of approaching a critical transition (Scheffer et al. 2009; Ufimtsev 2009).

In metaphors, the unity of diachronic and synchronous, dialectics of life, the difficulties of life “grasp” especially easily and harmoniously: a person gains access to understanding the value of his experience - both for himself and for those around him. In psychotherapeutic communication, where the unconscious is almost inevitably involved, the metaphorical

language of the narrative is valuable for a number of reasons (Arpentieva 2015; Arpentieva and Terentiev 2016; Bakurova 2015; Zinkevich-Evstegneeva 2012; Zinkevich-Evstegneeva 1998). It is more open to analysis and understanding; it is more powerful in terms of psychotherapeutic intervention, it gives the consciousness the opportunity to relax, and activates the awareness that are ignored by the patient in everyday life, also it reveals “weak signals” or markers of change and it can be used to create change as a trigger.

Metaphors allow us to comprehend the most complex, incomplete or ambivalent aspects of problem relations for a patient and a psychotherapist, including, in the context of the theory of archetypes/archetypal structures, to form on the basis of their analysis more productive in relation to a particular period of a person’s life in one or another community, and more conscious role models that underlie the “paradigm” of understanding oneself and the world (Briggs-Myers 1998; Chernyshov 2011; Fromm 2010). In technical terms, this means the use of techniques such as “fishing” and “the road of their breadcrumbs” by E. Mindell (Mindell 1997) “an amplifier of weak signals” or the analysis and transformation of archetypal and role structures of a person’s relationship to himself and the world. For these aims we the use of techniques similar to the analysis of projective techniques, including those developed by us to optimize the processing of TAT, “Self-attitude test”, “Rules of the three” test and other projective techniques (Arpentieva 2015; Harris and Zeisler St 2002; Mindell 1997; Ufimtsev 2009). In addition, the idea of “weak”, intertext signals formed the basis of our tales (Arpentieva and Terentiev 2016; Leskov 1981).

CONCLUSION

A metaphor in a person’s life acts as a signal and a trigger for change: its use, one way or another, reveals zones that are subject to changes and stimulates changes themselves. Metaphors manifest themselves in various archetypal structures and in specific metaphors of role models. They allow you to evaluate the direction of the patient’s internal movement towards the realization of a particular motivation, intention, support upward and/or slow down downward intentions, as well as comprehend how the patient perceives external changes, how he experiences stress of changes.

Chapter 425

COVID-19 POSSIBLE TREATMENT THROUGH EXERCISE AND NUTRITION

*Hamidie Ronald Daniel Ray**
and A. Firmansah Wargahadibrata

Universitas Pendidikan Indonesia, Bandung,
Jawa Barat, Indonesia

ABSTRACT

In December 2019, a public health emergency was induced by an outbreak of novel beta coronavirus termed 2019-novel coronavirus (SARS-CoV-2) in Wuhan City, Hubei Province, China. Since May 20, 2020, in Indonesia, there were 20.162 cases confirmed as positive for COVID-19. COVID-19 prevention and mitigation actions are the keys to implementation in health and community services. This paper aimed to provide some possibilities treatment through exercise and nutrition in order to improve immune system as a prevention to COVID-19. A weak immune response will occur due to fewer nutrients. If the nutrients with sufficient energy and micronutrients are adequate then the body's immune system will be strong. A home exercise program using different safe, simple, and easily implementable exercises is suitable to avoid the airborne coronavirus and preserve fitness levels due to the high risk of spread (by a person to person or contaminated surfaces).

Keywords: COVID-19, exercise, nutrition, prevention and mitigation actions.

1. INTRODUCTION

Virus disease is still emerging and is a serious public health problem. Several virus diseases include the severe acute respiratory syndrome coronavirus (SARS-CoV) from 2002 to 2003, and H1N1 influenza in 2009 was recorded. In December 2019, a public health

* Corresponding Author's Email: hamidieronald@upi.edu.

emergency was induced by an outbreak of novel beta coronavirus termed 2019-novel coronavirus (SARS-CoV-2) in Wuhan City, Hubei Province, China, which is going to be a worldwide epidemic with high mortality and morbidity (Pradhan et al., 2020) and the World Health Organization (WHO) declared an official name for the new coronavirus disease as COVID-19 (Hamidah, Sriyono and Hudha 2020; Anggraeni et al., 2020).

Since May 20, 2020, in Indonesia, there were as many as 20,162 cases confirmed as positive for COVID-19. The numbers of fatalities are 1,278, while the number of recovered patients is 4,838 and these cases still increases until now. Based on scientific evidence, COVID-19 can be transmitted from human to human through coughing/sneezing (droplets). The people at the highest risk of developing this disease are people in direct contact with patients with COVID-19, including those who treat patients with COVID-19. Standard recommendations for preventing the spread of infection are regular hand washing with soap and clean water, applying the ethics of coughing and sneezing, avoiding direct contact with livestock and wild animals, and avoiding close contact with anyone who shows symptoms of respiratory illnesses such as coughing and sneezing. Also, implementing Prevention and Control Infection while in health care facilities, especially at the emergency departments.

COVID-19 prevention and mitigation actions are the keys to implementation in health and community services. The most effective preventive measures in the community include maintaining hand hygiene by washing hands with soap and using running water or with a hand sanitizer; avoiding touching eyes, nose and mouth; applying the ethics of coughing or sneezing by covering the nose and mouth with the inner upper arm or tissue, then throwing the tissue in the trash; wearing a medical mask if you have respiratory symptoms and doing hand hygiene after removing the mask; maintaining a distance (at least 1 meter) from people who experience symptoms of respiratory distress.

2. PREVENTION OF COVID-19 THROUGH PHYSICAL ACTIVITY

Keeping your physical condition fit is an important thing to do, especially for people who are at risk of non-communicable diseases. However, on the COVID-19 pandemic like this, physical activity and space are limited. How could we work around this? Previous studies have shown that moderate-intensity physical activity has positive enhancing effects on immune system responses against viral respiratory infections (Halabchi, Ahmadinejad, Selk-Ghaffari 2020; Martin, Pence, Woods 2009; Harris 2011).

People who exercise with moderate-intensity physical activity suggested to increase in neutrophil. Furthermore, natural killer (NK) cell counts are detected and salivary IgA concentrations are enhanced (Halabchi, Ahmadinejad, Selk-Ghaffari 2020; Martin, Pence, Woods 2009). Moderate-intensity physical activity increases stress hormones, which leads to a reduction in excessive inflammation (Harris 2011). This leads to a boost in immunity in order to against viral infections via a change in Th1/Th2 cell responses (Pradhan et al., 2020). Twenty to thirty percent reduction of upper respiratory tract infections is reported in individuals performing on moderate levels of physical activity in their daily life. However, prolonged high-intensity physical activity leads to immunosuppression (Pradhan et al., 2020; Ahmadinejad 2014). Moderate intensity physical activity boosts the immune system and the risk of respiratory track viral infections is reduced. However, high-intensity physical activity

with long durations weakens the immune system for several hours following the exercise, and the risk of inspiratory track infection is increased in this period (Rondanelli, 2018).

3. SPORT HEALTH CHARACTERISTIC TO PREVENT COVID-19

Sports Health is a form of sports activities for health purposes. As a sporting activity, it is clear that it is working on the body or the body - (physical aspects). General characteristics of sports health are:

1. Easy: the movements are easy, so that it can be followed by ordinary people, which can enrich and enhance the ability and basic movement skills, for example the motion needed for the implementation of daily living activities.
2. Cheap: very minimal equipment or even no equipment at all.
3. Festive: able to arouse excitement and not boring.
4. Beneficial and Safe:
 - The benefits can clearly be felt, and it is safe to be implemented by each participant with different age levels and dynamic healthy levels.
 - The intensity is sub-maximal and homogeneous, not maximal movements or maximal explosive movements (safety factor).

Terms of the benefits and safety of health sports require special technical-physiological characteristics, namely:

1. Homogeneous and submaximal in intensity or sports load:
 - Sports are carried out with $\pm$ flat / homogeneous intensity
 - There are no movements with a load / intensity that is maximal,
 - No deployment of maximal capabilities.

A homogeneous intensity is needed to make it easier to regulate exercise dosages appropriately, while submaximal intensity is needed as a safety factor. In health sports, people are not required to make a maximum appearance, except when undergoing physical fitness tests. Health sports consist of units of motion that can (deliberately) be made to reach all joints and muscles and can be assembled to become a continuous movement (non-stop), which is an important factor to be able to regulate the dose and intensity of health sports.

1. A unity of measure (dosage): - can be regulated both in intensity (by adjusting the load/strength and/or the speed of repetition/contraction repetition), as well as the duration (duration) of its implementation (by adjusting the number of repetitions).
2. Adequate:
 - There are certain minimum limits for the intensity and timing of the exercise of health to produce benefits, in particular, to increase the functional ability of the Supporting Motion Equipment, held 3-5x/week (minimum 2x/week).

- It can reach intensities between 60-80% maximum pulse rate (Maximal Heart Rate / MHR) according to age. MHR according to age = $220 - \text{age}$. It is good for each participant to know how to set and calculate the pulse of each exercise.
- 3. No Stress Conditions: done with ease, without emotional burden, not competing with each other

4. SPORTS HEALTH TARGETS

There are three stages of health sports goals.

1. *Goal 1 - MINIMUM Targets*: In this first goal, the main goal is to at least maintain the ability of motion that is still there, and if possible try to improve the ability of motion by seeking an increase in area movement of all joints to achieve flexibility, through stretching and relaxation training as much as possible, without any jerks or snaps, which means mobilizing all joints. For example, people who are attached to a wheelchair must maintain and improve the ability of movement that still exists in all their joints, as well as maintaining flexibility and coordination ability, through movements such as Aerobic Gymnastics. Basic abilities (physical abilities) and coordination skills can be improved by requiring participants/students to follow the movements exemplified by the instructor as intensely and accurately as possible following their abilities.
2. *Goal 2 - Goal BETWEEN*: The goal of health exercise at this stage is to maintain and enhance the ability of muscles to maintain and improve their mobility further. The exercise is conducted dynamically and statically. Training in a dynamic way is to perform movements that are fast, repetitive, and antagonistic accompanied by a jolt to further “fill” the movement (the plyometric principle). The exercise of health sports must always be gradual and not exceed the capabilities at that time. Static training is by performing isometric contractions, but breathing must continue as usual (may not suppress breathing/straining), because it should be done part by part. As an example, first, an isometric contraction is done both the upper extremity and then the two lower extremities. Isometric contractions are maintained for 4-6 seconds repeated 3-5 times with active breaks in between. Active rest is intended as an auto-massage. A mistake that can be dangerous is when an isometric contraction is carried out at the same time for the whole body so that there is a kind of Valsalva maneuver (= straining), which will increase blood pressure so that it can be dangerous for health sport participants who have high blood pressure or have heart disease. Health sports training which has reached the Goal 2 stage will naturally include the Gold 1 stage because to train the strength and endurance of the muscles it must always go through joint movements. Therefore, the dynamic way is the most physiological.
3. *Goal 3 - MAIN Targets*: The main objective of health sports is to maintain adequate aerobic abilities or increase aerobic capacity to achieve a “medium” minimum category.

5. BODY IMMUNE FUNCTION AND MICRONUTRIENTS REQUIREMENT

The immune system is a system that works naturally in one's body. Immune system function is protecting the body against microorganisms, infections and harmful substances from outside the body. This self-protection system consists of three layers, namely:

- Physical (for example skin, epithelial layer along the airways and gastrointestinal tract) and biochemical (for example mucus and stomach acid),
- Various immune cells: granulocytes, CD4/CD8 T cells and B cells,
- Antibodies, e.g., immunoglobulin.

This first line of defense system is commonly referred to as innate immunity, which is a combination of physical and biochemical protection (Castelo-Branco and Soveral 2014). In the case of the COVID-19 which enters through the skin from a handshake, the body will respond by activating this first layer of self-protection system. When COVID-19 successfully passes this first tier, then will face various components of the second layer of T cell and B cell. In the case of the above there are two consequences that will occur, depending on the functioning condition of the immune system of the person, namely:

- First, when the immune system function is strong then the individual will be painless and there are no symptoms, or mild pain such as mild cold symptoms, muscle aches, bloating and diarrhea, but a few days later back healthy.
- Secondly, if the immune system function is weak then the individual will experience the symptoms of COVID-19, even one to death.

Both systems also protect against cancerous or precancerous cells. The immune system function is also influenced by the age factor. In infants and children, the system is newly developed and has not been functioning. In adulthood, the body's immune system is already functioning maturely. In elderly people, the system will gradually experience a decline in function (Rondanelli et al., 2018). Common symptoms that are perceived when the immune system decreases are fever, colds, and diarrhea. Even in the age of adulthood, the function of the body's immune system is mature, its strong or weak condition is strongly influenced by the adequacy of energy and micronutrients, or nutrients, derived from food. If the nutrients with sufficient energy and micronutrients are adequate then the body's immune system will be strong, and conversely if less it will be weak. Energy supply can be obtained from foods with adequate carbohydrates, protein, and fat content. Whereas micronutrients that are important to enhance the body's immune system are vitamins A, C, D, E, B2, B6, and B12, folic acid, beta carotene, iron, selenium and zinc (Alpert 2017).

Aside from the adequacy of energy and micronutrients, other factors are also important for the immune system. This factor is emotional stress, which will increase cortisol (a type of stress hormone). Heavy stress and stress that occurs for a long time, will weaken the immune system. In this condition, the body will also need a micronutrient substance above in larger quantities, so that the immune system can function optimally. Emotional stress occurs as a result of a person's mindset that is fraught with fear, excessive anxiety, and often negative thinking. The COVID-19 pandemic condition is at risk of triggering the negative flavors

above which ultimately cause emotional stress which is the consequence of weakening the body's immune system. This condition will cause a person's body to be a high risk for contracting and suffering from the symptoms of COVID-19.

There is a close relationship between nutrients, infections, and the body's immune system. A weak immune response will occur due to fewer nutrients. There is a contact history with infections, and a malnourished physical condition (Calder 2013). It is clear that optimal immunocompetence depends upon nutritional status (Watson, Zibadi, and Preedy 2010). It has been reported by researchers that micronutrient deficiency is a common factor in the world (Biebinger, Hurrell, and Ottaway 2008). Micronutrients are often not noticed by the layman, even by medical personnel, because of the enormous amount and need to be consumed in the long term, and the given effect is not realized in the improvement. For example, if we are rarely sick this is an extraordinary blessing of life, but many people are unaware of it. The use of micronutrients as primary therapy has not been a standardized medical procedure, whereas there have been some reports stating that therapy with micronutrients can provide a corrective effect on the health of a person, even in those who are experiencing certain diseases.

In one case, X, experiencing similar symptoms to that of autoimmune sufferers: weak muscles, bloating, and digestive tract body often not fit. Apparently, after being checked, X has a deficiency in blood levels of vitamin D. After being administered vitamin D for three months, the blood vitamin D levels gradually increased to normal, increased muscle strength significantly, bloating becomes rare and the body is more fit, becoming less flu pain. It is an example of a good case, to see the relationship between vitamins and the immune system. Until now, X is still a consume vitamin D and still performs a vitamin D blood test regularly and health conditions are better than before.

The following will display some types of micronutrients that are beneficial to the function of the immune system and various food sources. And it will be explained which micronutrients are somewhat difficult to digest and are processed by the body, so it needs to be considered obtained through the supplement.

Vitamin A, stand out from the color aspects of the food, is colorful. This colorful food source contains carotenoids. Food sources with high carotenoid content: carrots, yam, pumpkin, egg, and deep-sea fish. Our body can convert carotenoids into vitamin A which serves as an antioxidant and strengthens the immune system function of the body against infections. Vitamin B12 is a vitamin that helps the formation of energy in the body. Food source with vitamin B12 content: Red meat, clams, oysters, and eggs. The body needs carbohydrates, proteins and fats to form energy so that energy production can be optimal, hence this is the role of vitamin B12. If the body is deficient in vitamin B12, then the body will feel less energy and tired quickly.

Vitamin C is the most popular and well-known vitamins in society. It is known that vitamin C is essential for the functioning of the immune system. Food sources with high vitamin C levels are papaya, strawberry, orange, lemon, broccoli, kale, spinach, and green leaves. Furthermore, vitamin D is a vitamin commonly referred to as the sun's vitamin. It is generally known that sunbathing at 9 a.m. will increase vitamin D in the blood. Although it increases, not necessarily the level of vitamin D blood is sufficient to support the function of the immune system. This is because vitamin D obtained from the food and the sunbathing process should still be processed in the liver organ to be vitamin D active. Most Indonesians have problems digesting vitamin D food sources and also process problems in the liver

organs, so it is necessary to check the blood level of vitamin D and consult the doctor. Food sources with high vitamin D content are deep-sea fish, salmon, sardines, tuna, fish oil, and krill shrimp oil.

Vitamin E is a vitamin that is already known for the health of our skin. It also works to help the body fight infections. Food sources with high vitamin E content spinach, broccoli, almonds, peanuts, cashews, and sunflower seeds. Folic acid, a vitamin that helps the formation of new cells, is essential for cells involved in the immune system. Food sources for folic acid are kidney beans, black beans, white beans, peas, and other foods added folic acid supplements. Iron is a blood-enhancer vitamin that has been well known by the people of Indonesia. Blood will bring oxygen and distributed to all parts of the body. Food sources for iron are chicken, duck, turkey, red meat, liver, kidney beans, black beans, broccoli, kale, and various seafood.

Additionally, selenium is an important vitamin in enhancing the functioning of the immune system. It includes for its effect on lowering the over-active response of the body in the case of terrorism, therefore selenium is also known as a vitamin for cancer. High-feeding sources of Selenium are Brazilian beans, broccoli, garlic, sardines, tuna, and barley. Zinc, a vitamin that helps the body's immune response and also lowers the inflammation that occurs in various diseases. Food sources are high in Zinc levels: oysters, clams, crabs, low-fat meats, chickens, ducks, red beans, and Arabic beans.

CONCLUSION

As a conclusion, moderate-intensity (and not high-intensity) exercise may be helpful for healthy asymptomatic people and should be recommended. However, as mentioned earlier, due to the high risk of spread (by a person to person or contaminated surfaces), an exercise in private environments (at home) with good ventilation and use of personal equipment may be more reasonable. A home exercise program using different safe, simple, and easily implementable exercises is suitable to avoid the airborne coronavirus and preserve fitness levels. This program may include aerobic (walking in the house), strengthening, stretching, and balance exercises, or a combination of these (Chen et al., 2020).

ABSTRACT

The stress of change is comprehended, experienced, and passed by a person depending on the sociocultural situation, especially facing corona virus disease 2019 (COVID-19) pandemic. This pandemic influence how people lives, changing traditions and stage of development of society. Scenarios and human life stories in the COVID-19 pandemic include many points of change and transformation, including changes associated with external and internal deformations and dangers, such as bodily somatic and other diseases and disorders. These points form narratives - a multidimensional and multicomponent phenomenon. The aim of the study was an integrative analysis of anticipation and minimization of the stress of changes in the life of a person (patient) in the context of the analysis of sociocultural changes. The research method was a systematic theoretical understanding of the problems of anticipating and minimizing the stress of changes in the life of a person (patient) in the context of the analysis of sociocultural changes. The main results of the study showed that archetypes and role

* Corresponding Author's Email: asnul@utm.my.

models are of great importance in the analysis of the sociocultural aspects of understanding, experiencing and undergoing the stresses of change. Moreover, role models, unlike archetypes, according to researchers, can be classified based on a comparison with the basic motives of life. In addition, human communities go through developmental levels, which manifest themselves as different approaches to solving the problems that reality poses for them.

Keywords: archetypes, narrative psychotherapy, markers of change, stress of change, triggers for change, weak signals

1. INTRODUCTION

Scenarios and human life stories include many points of change and transformation, including changes associated with external and internal deformations and dangers, such as bodily somatic and other diseases and disorders. These points form narratives a multidimensional and multicomponent phenomenon. Participants or heroes of narratives (narratives of change or narratives of stress of change) live in a number of spaces and times, a number of worlds intersecting with each other, changing their understanding of themselves, others and situations of interaction (Arpentieva 2015; Jung 2003; Khlebnikova 2013; Meadows 1999; Meadows 1999). Therefore, in working with stresses of changes) and narratives describing them, aimed at understanding and anticipating (“foresight”) stresses of changes in order to minimize them, special attention should be paid to combinations of diachronic and synchronous analysis. One of the incidents currently occurring is the Corona Viruses Diseases 2019 (COVID-19) pandemic (Anggraeni et al. 2020), which made online learning popular in the education system worldwide; it is discussed that not all teachers were ready to provide online lessons during this COVID-19 pandemic time (Arlinwibowo et al, 2020). However, online education has certain advantages for both teachers and students. Teachers should focus on its benefits in order to develop educational process and students' competences (Asnul Dahar Minghat et al., 2020; Kassymova et al, 2019).

COVID-19 is a disease caused by the corona virus. This virus first hit China in the city of Wuhan. This virus can infect the human body and cause death (Maryanti et al. 2020a, Maryanti et al. 2020b). Currently, the COVID-19 virus pandemic is hitting various countries in the world. The spread of COVID-19 does not only have an impact on health problems (Machmud and Mighat 2020). The spread of this virus has implications for problems in other aspects of human life and the country (for example, education, economy and social). The government has made various policies on preventing the transmission of COVID-19. The community limits various social activities outside the home (Putra and Abidin 2020). The danger of COVID-19 has made a large part of the community experience fear. In addition, the education process creates tangible level of stress by itself. Especially, when academic assignments are too much to be completed in a short period of time (Kassymova, 2018). However, there are different stress management techniques for students to cope (Kassymova et al., 2018). In fact, most people experience stress with the various changes that are made. This results in most of the illnesses suffered by them because of the suggestion of fear they have. They need an understanding of how to deal with and respond to various problems caused by this pandemic.

Changing patterns of behavior and the essence of the actions of participants at different stages of their life paths, in different worlds and times. Particularly great attention in this context should be given to metaphors - denoting worlds and times, as well as - accomplished or emerging transitions between worlds and times. Metaphors act as bright signals and triggers of change (Forrester et al. 1977; Loveridge 2009; Van Ray 2011). Each metaphor is a germ or designation of intention, which the heroes follow on their way to themselves, to each other and to God, to happiness and the resolution of the crisis.

2. PURPOSE AND METHOD

The aim of the study was an integrative analysis of anticipation and minimization of the stress of changes in the life of a person (patient) in the context of the analysis of sociocultural changes. The research method was a systematic theoretical understanding of the problems of anticipating and minimizing the stress of changes in the life of a person (patient) in the context of the analysis of sociocultural changes.

3. RESULTS OF THE STUDY

The stress of change is comprehended, experienced and passed by a person depending on the sociocultural situation in which he lives, on traditions and stage of development of society.

Archetypal Metaphors in the Work of a Narrative Therapist

Despite the huge variety of narratives, they highlight the main stages and moments inherent in any life narrative and form an algorithm (Zinkevich-Evstegneeva 2012; Zinkevich-Evstegneeva 1998; Zinkevich-Evstegneeva 2013).

The algorithm of life stresses or changes usually includes:

- Life in the “father’s home” (appropriation of parental experience, understanding the world, building relationships with worlds, people - life support),
- Parting with the home (voluntary or forced start of the path),
- Choice of road (crossroads and a choice corresponding to the goal of the path),
- Verification (for “good” or “evil heart” - selfishness or mutual assistance),
- Meeting with future helpers (friends who can help),
- Struggle and victory (achieving the goal of the path and fighting with personified evil, as a result which man becomes stronger and wiser or, on the contrary, succumbs to evil, weakens),
- Returning home (difficulties of going back, meeting a hidden evil, death when applying the old experience),

- Rebirth (death of the past, illusions, infantilism, discovering new creative abilities, strength and wisdom, help from friends, victory inside and out),
- Arrival home (a changed home, changed relationships, help from friends and the last trials, restoration of justice and roots that will serve as a support for him in further adulthood), a new image (change about Faces - Transformation: forgiveness, acceptance of the world, the path to a new future with an “open heart”),
- A wedding or a coronation (victory celebration, new social status, objectives, greater responsibility).

Each stage is important, meaning, forming stages, each of which has its own meaning, which can be revealed by asking the patient a series of questions (Beytson 2000; Zinkevich-Evstegneeva 2012, Zinkevich-Evstegneeva 1998). The description and problems of choosing behaviors are well demonstrated by archetypal and other typologies of personality development and its relations. These personal models describe the development of a person and human communities in terms of their belonging to certain generations, their social myths and archetypal figures and scenarios (narratives). The theory of archetypes, created by K. G. Jung on the basis of mythological narratives, was abroad. It developed in the typologies of J. Myers-Briggs, E. Schwartz, E. Bern, and others (Beck and Cowan 2005; Beck and Cowan 2010; Graves, Cowan and Todorovic 2005; Frants 1998; Fromm 2010; Jung 1996). Currently, the theory of archetypes is an effective and efficient tool for creating successful brands and advertising, as well as developing innovative areas of psychotherapeutic care. Based on their work, practitioners and theorists often distinguish a number of basic models of behavior and archetypes as systems of partially conflicting basic needs (intentions), as well as combinations that implement them. Often distinguished archetypal figures and scenarios can also be classified (Briggs-Myers 1998; Jung 2003; Lewin 2000; Meadows 1999; Jung 2003).

In Russia, a detailed typology of the archetypes of A. V. Chernyshov deserves special attention. Studying and analyzing fairy narratives, he revealed a number of characters corresponding to archetypes: Mother (Stepmother), Bogatyr, Lefty/Craftsman, Tsar/King, Koschey, Goldfish, Soldier, “Beautiful Vasilisa”, “Fool Ivan”, Prince Ivan, Damn, Baba Yag/ Witch (Chernyshov 2011). Many of these archetypes are similar to the archetypes of C. Jung et al. A. V. Chernyshov analyzes the ancient Russian folk tales and myths. However, he did not find complete coincidences of all archetypes and names; in particular, he did not find a clearly defined archetype (ideal image) that would correspond to the archetype of Creativity. The archetypes of the Goldfish and the magical qualities of Beautiful Vasilisa, creating the world and wonders, are somewhat similar to him.

Creativity acts as a process of implementing a project, a dream, a representation, the process of transforming an unstable imaginary object into some materials. This is reflected in a much later fairy tale tradition, in an author’s fairy tale. This is personifying in such images of Russian craftsmen from the people as Levsha/Craftsman of the N.S. Leskov (Jung 1996 or Master Danila of P. P. Bazhov (Bazhov1993). When analyzing narratives, “fabulous” archetypes help to expand identity and balance different intentions in the patient’s relationship with himself and the world. However, not all archetypes are combined, which sometimes causes an internal go or even an external conflict, a misunderstanding of the need for a particular type of behavior/attitude, and the need for change (Chernyshov, 2011). The archetype can become a design, a way of realizing significant or probably significant for the

subject of intentions: changes, attitudes or understanding (Chernyshov, 2011, Jung 1996; Jung 2003).

At the very beginning of their research, K. G. Jung wrote that the field of archetypes is not limited, archetypes pass into each other, and the archetype itself is a definite “tendency to form a representation of motive” (Jung 2003). At the same time, archetypal structures include both positive and negative traits, which is quite consistent with the reality of human life, but can form obstacles for people to understand each other, for changes, making what is happening between patients and the therapist, patient and other people ambiguous and blurred. Moreover, the archetype as a super cultural concept is characteristic of all humankind, for each person in one way or another. Therefore, appeal to archetypes does not guarantee that their use will be effective, and the use of archetypes in themselves in psychotherapy is sufficiently motivating to transformations.

However, it is impossible and unproductive to ignore the cultural context. Narrative therapy can be quite successful, productive, and effective if you use not so much the archetypes as support and transformation, but role models — some reference (unambiguous) sets of behavioral patterns that have typical characteristics and act as role models. The role model, like the archetype, has super cultural significance, however, it is not necessarily addressed to the collective unconscious and is included in the process of socialization of a person to one degree or another fully and intensively, depending on the characteristics of the cultural context.

In each culture, role models have special and common features. The main thing in them is the possibility of forming a reference sample and an important, from the point of view of the psychotherapeutic process, design of the stereotype of the carrier of other role-playing behavior. The role model is significant as a specific way of implementing a motive, and, more broadly, of a person's self-expression, designation of his life beliefs in a specific context of life. The role model applicable in psychotherapy can be considered as a potential image that a person may have a desire to play, that is, demonstrate to people around. And it can become the basis of a new way of life. Moreover, role models, unlike archetypes, according to researchers, can be classified based on a comparison with the basic motives of life. Role models correspond to different situations of life and, importantly, do not have conflicts with the cultural context, as they can be used as specific, and as super cultural, but with a specific embodiment in a specific cultural environment.

The Development of Metaphors - Models for the Development of Archetypes

The archetype or role model, with all its “timelessness” and “super culturalism,” is more or less specific, representing in the conscious and unconscious patient certain aspects depending on the time and space of his life. One of the interesting approaches to taking into account the diachronic and synchronous aspects of role models, understanding the cultural and historical features of their forms and contents, their relevance and realization, is provided by the so-called “spiral dynamics”, which is based on the work of the American psychologist and philosopher of the 60s of the XX century Cl. W. Graves (Beck and Cowan 2005; Beck and Cowan 2010; Graves, Cowan and Todorovic 2005; Ufimtsev 2009). He investigated the “emergent cyclical levels of existence” that “adult biopsychosocial systems” are subject to,

believing that human communities go through developmental levels, which manifest themselves as different approaches to solving the problems that reality poses to them.

At the same time, the models of behavior described by him change depending on the cultural and historical space into which a person falls (Hamidah et al. 2020; Dirgantari et al 2020). Each stage of its development in this space is characterized by a specific system of values, different cognitive attitudes (“cognitive points” or strategies for understanding oneself and the world) and different behaviors. At the same time, each next level is not so much crowding out the previous one as it is superimposed on it: all previous levels of development continue to exist along with the most recent one. Cl. Graves argued that in usually societies one or another paradigm prevails, which is the “cognitive glasses” through which society looks at the world. It is subject to change, because, helping society to solve some problems, it raises others before it, the solution of which requires a paradigm shift. This process is not accidental and the following paradigm is in certain dialectical relations with the previous one, hypothetically described as a spiral of two turns, on which there are a number of nodal points. Each paradigm does not completely replace the other; it only supplants it from a dominant position. This transition is not just “rebranding”, but the process of changing identities that are not related to each other as levels of development (Graves, Cowan and Todorovic 2005).

Later D. Beck and Cl. Cowan (Beck and Cowan 2005; Beck and Cowan 2010; Graves, Cowan and Todorovic 2005) noted that communities of people are carriers of memes (cognitive structures), among which a special, decisive role is played by “valuememes” - in their designation, v-memes (values-memes). Value memes or “supermemes” attract lower-order memes that define cognitive habits, as well as actions as methods for solving life tasks and problems accepted in a given community, at a given age, etc. (that is, in fact, role-playing models). The prevailing supermem gives rise to a new supermem, which gradually replaces the previous one, moving to the “shadow” or marginal areas of mass and individual consciousness. Usually a movement is realized from one level to the next, located higher on a spiral, but a downward movement, “degradation” to lower-level values is also possible. Each level is associated with its own supermem, endowing a person with its worldview and values. Each level is characterized by its own understanding of itself and the world, which affects more or less conscious aspirations (intentions) and the choice of behavior patterns (response to problems) (Ufimtsev 2009; Van Ray 2010).

A change of levels occurs when a person or society accumulates tasks that cannot be solved within the framework of the current level (Graves, Cowan and Todorovic 2005; Pekar 2010; Scheffer et al. 2009). D. Beck and C. Wilber introduced the concept of “spiral masters” - people and communities who have reached the “highest level” of the spiral and have the ability to control all other communities. However, still Cl. Graves warned that his levels are no more advanced among less developed people and groups, but simply different value systems and ways to solve problems. That is, “spiral masters”, including in psychotherapy, are people who are able to reflect and use the potential of each stage and changes in the community for the development of man, his relations with himself and the world (Beck and Cowan 2005; Graves, Cowan and Todorovic 2005; Wilber 2013). Described by Cl. Graves and colleagues, the particulars of understanding the world and the intentions of changes at each level, as well as the theory of generations, can serve as the direct basis for the development of role models.

4. DISCUSSION

A similar model of the behavior patterns of different types of people, their development over time, in different historical and political periods, is presented in the theory of generations developed by W. Strauss and N. Howe (Howe and Strauss 1997). They believe that there are “generational cycles” that reflect a repeating pattern of behavior of different types of generations in which one or another “age identity” dominates. People of each separate age group (cohort) tend to share a special set of relationships and values, perceptions (“cognitive points”) and patterns of behavior and communication, insofar as they grew up in the same historical conditions.

At the same time, representatives of each generation experience a sense of belonging to their generation and subjectively share one historical era: they are faced with the same historical events and social trends, being in the same phases of life; they share certain general ideas and relationships, as well as patterns of behavior and communication. Since each generational period lasts 20–25 years, four periods make up a complete cycle lasting approximately 80–90 years: it is called *sakuala* (saeculum) - the “natural age”. According to the survey of centenarians, a new cycle or “natural age” begins at the age of 90: the cycles tend to repeat, reproducing in the individual development the stages of youth-adulthood-old age. In addition, in some cultures, people predominate whose psychological age does not rise above that of children (many “primitive” cultures“), and in some (Tibet, India) there are many psychologically” old “people. Therefore, the result of various processes and layers of a person’s relationship with the world is very diverse, although it is not devoid of trends, the consideration of which can help resolve development crises, intergenerational conflicts and development crises of civilization as a whole.

In general, researchers identify a number of generational archetypes that are repeated sequentially, creating and maintaining the rhythms of the crisis/awakening cycle: idealist, responsive, civic and adaptive (Howe and Strauss 1997). Work with people of different generations, therefore, must take into account generational intentions and models, those problems that are associated with the birth, life and death of a person in certain periods of time. At each moment in time in the inner space - the time of man - there are several alternative “paradigms” or models at the same time. In turn, each of them gives rise to a family of templates, which together form an understanding and attitude to various life problems. During the life cycle of each model or paradigm, it gives rise to several other models and paradigms that go through their shorter life cycle - from the stages of ascension to the stages of decline. The psychotherapist’s task is to connect the patient with the myths or models that are at the apogee stage and regularly “transplant” it with the “descending” one, which has demonstrated its limitations and errors, the paradigm on another, “upward”, giving a more developed, complete and accurate understanding of oneself and the world.

Understanding archetypal and more specific metaphors, including role models implemented by a person in his life, allows us to evaluate the direction of the patient’s internal movement towards the realization of a particular motivation, intention, support upward and/or slow down downward intentions, reduce the level of negative impact of stress of changes (Arpentieva 2015; Meadows 1999; Meadows 1999; Ufimtsev 2009). Turning to the study of patient’s narratives and metaphors, with all its external simplicity, requires a specialist to have a good knowledge of himself, highly qualified: an individual approach,

empathy and intelligence of the psychotherapist himself, his willingness and ability to see the “truth” of a person, life, himself (Arpentieva and Terentiev 2006). In addition, the idea of “weak”, intertextual and intertextual signals can be laid in the basis of psychotherapeutic stories/fairy tales (Arpentieva 2015; Arpentieva and Terentiev 2006). In them, “weak signals” take on their own names (Bakurova 2015; Harris and Zeisler 2002; Hilborn 2004). The simplest and most common concept becomes a metaphor for another concept or a whole group of concepts. These are metaphors of Path, Light, Love, Change, etc. they are fill the space of fairy tales in such a way that, in fact, they act, along with the main characters. Thanks to such stories, the patient, as a reader or even as the author of the story, tunes in to the fact that the story he will study has much more meanings than it might seem he himself becomes a seeker and conceptualizer of the metaphors with which he resonates in the process narrative psychotherapy.

CONCLUSION

Classical predictions of a person’s development, changes in his life, including changes in psychotherapy, are based on the quite logical idea that small, weak changes usually produce small results. They underestimate or simply ignore weak signals, focusing on indicators of the strength of trends and probabilities. However, many phenomena do not fit into statistical trends. Oscillations on the border of chaos is a rich environment in which weak signals can most often be detected (Minigalieva 1999; Minigalieva 1999). If you teach a person or group to recognize the border and balance between areas of order, structure and randomness, uncertainty, they gain the advantage of understanding to see and take into account weak signals and those trends that stand behind them. The richest source of weak signals is the periphery of culture: 1) interdisciplinary, inter-traditional; 2) kitsch and simulated, pseudo-art and pseudoscience; 3) extra-traditional, cultural, anti-science and anti-art. That is, rejected and forbidden, unusual and rare, devoid of price - worthless and priceless, and magical, fabulous, which is why narrative therapy has the most significant psychotherapeutic potential among other types of psychotherapy.

Chapter 427

ADJUSTMENT OF THAI CURRICULUM AND INSTRUCTION IN THE COVID-19 CRISIS

Sutthiporn Boonsong*

Faculty of Technical Education, Rajamangala University of Technology Thanyaburi,
Klong Hok, Klong Luang District, Pathum Thani, Thailand

ABSTRACT

The crisis from COVID-19 has a big impact on the education sector both in Thailand and abroad. Educational institutions, including tutoring schools and various skill schools, were closed. During this stage, both the schools and many universities have begun to consider postponing the entrance exam, changing the curriculum, and making the online examination to reduce the risk of student gatherings. This includes the graduation ceremony as well.

Therefore, educators or educational policy administrators under the emergency situation of COVID-19 should consider not only accessing to online teaching but also changing other teaching methods during the COVID-19 crisis. Traditional methods might be used to support local areas that cannot access online education effectively. The person responsible for Thai education must also concern the context of inequality and disadvantaged children in society. Thailand is not the only country in the world that has this problem. Many countries face with this problem together and are able to learn lessons and solutions together.

Keywords: COVID-19, education adjustment, Thai curriculum

1. INTRODUCTION

A crisis happens from the COVID-19 pandemic after the World Health Organization (WHO) declared it a serious pandemic (Anggraeni et al. 2020).

* Corresponding Author's E-mail: sutthiporn_b@rmutt.ac.th.

One way to deal with an outbreak is through social distancing or maintains physical distance in society in order to break the chain of COVID-19 spread from person to person.

Figure 1. Online teachers meeting and instructions in the COVID-19 crisis.

The social distancing has a significant impact on all levels or sectors (Hashim et al. 2020). Adaptation to survive has been happening both in Thailand and abroad. The pandemic has influenced the education sector as well. Online teaching system has been adopted in order to conduct teaching and learning (Figure 10.1). Schools and universities have started to consider postponing the exam and switching regular to online classes to reduce the risk of student gatherings on the test day. It also includes the adjournment of the graduation ceremony as well. The state declared tutoring schools and vocational schools to also start providing online education (Bangkok Busyness 2020).

Activities to promote skills and knowledge such as a science camp and summer camps in foreign countries are also affected. Postponing travel is also considered to be the safest under unprecedented situation and to reduce the risk of virus infection.

2. ADAPTATION OF THE THAI EDUCATION SEGMENT

As mentioned earlier that COVID-19 has affected education sector, therefore, the Ministry of Higher Education, Science, Research, and Innovation (MHESRI) of Thailand announced the request for cooperation with educational institutions affiliated with MHESRI. The cooperation includes (Marketingoop 2020):

1. Reducing the rental fee for small business operators in the university.
2. Reducing student tuition in this upcoming semester.
3. Reducing other expenses which is not urgent in order to increase the employment of students and general personnel.
4. Preparing online learning and teaching (Mulyanti et al. 2020).
5. Reducing various service fees charged by Small-Medium-Sized- Enterprises, startup, and the general public as special case.
6. Higher education institutions consider and assess suitable steps to support those impacted by the additional incidents.

In addition, Thai universities have released different initiatives to respond to the COVID-19 crisis. As an example, "Srinakharinwirot University" has announced guidelines for teaching and learning to prevent the spread of COVID-19. At the end of the announcement stated that:

1. Teaching and learning management help teachers to adapt the assessment and evaluation of teaching styles as necessary.
2. Final examination allows teachers to adapt appropriate and effective methods of measurement and evaluation that can use the original format test or other methods.
3. Examination at the graduate level can be adjusted using the online examination or teleconference program.
4. All non-urgent tasks should be postponed, but, if a justification is required, the faculty should plan the screening/prevention/control of infectious diseases (COVID-19).
5. Implementation of the teaching and learning model adjustment and final exams to avoid the spread of COVID-19 are exempted from checking the number of courses attended by at least 80%.
6. Implementation of the teaching and learning model adjustment and graduation final exam and other activities.

Therefore, teaching and learning in the COVID-19 era is one of the challenges for teachers encountered. They have to find ways to transfer knowledge through new channels as the traditional lecture in the classroom is no longer available (Sangsawang 2020). One approach is to build online lessons using internet technologies and different software, but the key issue is the infrastructure. In some countries, as we know, the digital basics are not quite excellently-supported to all teachers. According to the 'Teacher Tapp' survey, which surveyed the teaching of more than 6,000 teachers in the UK, it is found that teachers in public schools can publish less online lessons than that in private schools.

Taking into account for 40 to 69% of respondents indicates that the availability of tools in public schools is much slower than in private schools (Thanalerdsomboon 2020).

In addition, some teachers do not have enough knowledge or expertise to use technology. Some subjects, such as physical education, are not familiar with tools which are not suitable for online teaching. Therefore, it is difficult to adjust the design of new teaching methods to keep things up to date. In regards, some students are not able to access online lessons effectively due to the lack of equipment and the quality of the network signals. Furthermore, it is still found that most students continue to show less ability when studying online, so

learning online may not be the best option for long-term studies. Unless, the curriculum designed for this type of teaching approach has been prepared from the outset. However, problem-solving strategies for changing educational problems will have to consider important issues such as the World Economic Forum projected that the world of education will change in the future schools (Thanalerdsomboon 2020).

1. We will see educational development and changes in the lifestyle of learning
In the past, almost all educational structures around the world stayed in the classroom and had schools was the main center. However, many educational institutions will continue to implement new technologies in the future to replace classroom teaching. Within a short time, there will be several developments for education, and there will be different types of access to information. Resulting in a learning lifestyle outside the classroom, we do not adhere to the conventional school hour schedule which may mean that 'Learn Anywhere, Anytime' is one of the everyday practices.
2. We will see cooperation from many parties to improve education.
COVID-19 crisis phenomenon allows us to see cooperation in developing educational systems from many sections. In addition to teachers and educational stakeholders, there are governments, media, scholars, and various service providers of communication networks, technology developers, in which they help build a platform database system. Many interactive learning platforms considered a positive indication that the education system would be able to progress much far from brainstorming and collaboration like this condition in the future.
3. We must reduce the inequality of access to digital technology for equal education.
In the future, online classrooms (that play a greater role in the classroom) create a secure comprehensive infrastructure, and enhance access to technology. All aspects of innovations that the education system is currently using such as 5G will help all groups of children to have equal education or at the very least causing most children to have a better education.

3. CONCLUSIONS TO BE CONSIDERED FOR EDUCATION MANAGEMENT TO SUPPORT THE COVID-19 CRISIS

According to data collected in 2018 by The Organization for Economic Co-operation and Development (OECD) (Margetingoop 2020), it is found that Thailand still has an inequality access online learning, such as in-house study sites, computer, notebook, and tablet. Particularly, it happens when comparing between rich and poor families. In terms of digital divide, there may be exceptions for accessing television, mobile phones, and smartphones. It seems that all families can access these digital devices. This information can be used as sources of knowledge for educators or policy executives regarding the emergency COVID-19 crisis in order to address the online access to make teaching and learning (Margetingoop 2020).

However, Thailand is not the only country in this world facing the same problems. Many countries also encounter a similar problem, so each country should learn from each other and

work together to find solutions. Therefore, the conclusions that could be considered in order to handle education during the COVID-19 crisis (Tongliemna 2020) are written as follows.

The Use of Radio and Newspapers

The use of radio and newspapers are the most traditional method in the United States. Schools were closed because of the polio outbreak in 1937, causing 325,000 elementary school students to leave the school. In that era, the use of broadcasting on the radio with homework questions sent to the newspaper every morning. There were qualified teachers to check the lesson contents, and experts were invited to broadcast and used the hotline system so parents could call for consultations. There were about 20 teachers waiting to answer the call with parents interested in calling on all the time to make comments. Parents were given support to help children to do homework by taking lessons with children. However, there were also problems. As an example, some houses did not have a good radio signal, so they had to move from outside the city where radio signals. Another problem was uneven learning speeds that are not much different from the era of Internet use. Despite being more convenient, unequal access has problems.

In countries where students have difficult situations for accessing communication devices as during the Ebola crisis in 2014. During that time, West African region shut down schools and delivered the education via radio. They also used text messaging where they shared educational news via mobile phone using Short Message System or short video transmission that uses less internet signals.

Television Use

During school holidays, China has a television program for students at different levels to learn on the screen by dividing the channel, channel schedule, date, time by grade level and by different subjects. It is considered the most accessible method for students without internet or computers. Although it is one-way communication, many countries use television as one of the educational channels, such as Greece, New Zealand, Educational TV channels in some U.S. states and British BBC television Discovery television station that focused on education. In Thailand, the teaching system via satellite television (DLTV) has long been used, and there is a fairly complete database and operating system.

Using a Document System (Learning Box Set)

Using the learning document method by using a series of books or lessons and various activities are the traditional way. Students can study on their own or combining it with other methods, such as providing homework and then having time to ask questions or discuss online. In Portugal, the documents are sent to students by mail including the homework. In China, parents who worry their children spend too much time on the screen could learn to

read or work by typing documents. In New Zealand, when the school is closed the printing and distribution on educational materials has increased because they send it to students.

The Context of Inequality and Disadvantaged Children in Society

Regardless of the method used in the teaching and learning during the COVID-19, it is important to choose the appropriate approach according to the context and readiness of the learners and instructors. Apart from academic concerns, the main concern is that school should be cautious and helpful to the students who might be absent for a long time due to the closure of the school. In times of COVID-19 crisis, school should be giving importance to the mental, emotional, and social conditions of the students as well. Teachers and schools should make students feel comfortable, feel they are not abandoned by the teacher, and in times of crisis, they are still part of the school.

Furthermore, Thai education should continue to think about students in special education classes, people with disabilities, people with learning disabilities, students whose parents or guardians cannot support them because they must work to earn money, students in a poor environment, and students live in domestic violence. How are the government and schools going to better assist those students? This is because children need special support in these communities and simply cannot wait for such a long crisis.

CONCLUSION

The crisis from COVID-19 has a big impact on the education sector. Therefore, educators or educational policy administrators under the emergency situation of COVID-19 should consider not only access to online teaching but also other teaching methods during the COVID-19 crisis. Traditional methods might be used to support local areas that cannot access online education effectively. The person responsible for Thai education must also consider the context of inequality and disadvantaged children in society. Thailand is not the only country in the world that has this problem. Many countries faced with this problem together and are able to learn lessons and solutions together.

Chapter 428

EDUCATION AND INFORMATION ABOUT COVID-19 FOR IMPROVING STUDENTS WITH SPECIAL NEEDS KNOWLEDGE IN INDONESIA

***Rina Maryanti, Asep Bayu Dani Nandiyanto,
Achmad Hufad and Sunardi***

Universitas Pendidikan Indonesia, Bandung, Jawa Barat, Indonesia

ABSTRACT

Students with special needs have several challenges in various developments and academics aspects. They need special treatments and ways to understand realistic conditions. At the time this research conducted, an outbreak of the coronavirus diseases 2019 (COVID-19) is spreading in Indonesia. Providing information and education about the COVID-19 is very important, especially for students with special needs in Indonesia. It is very crucial since special needs students are easily infected with the COVID-19. Most of them have low self-development skills (for example, rarely washing their hands, weak immune system, and not keeping the body and the environment clean). They need guidance on how to against the COVID-19 and how to improve their awareness, as well as how to avoid and reduce virus transmission. They can get education and information about the COVID-19 from the family, school, and community. Various questions were asked to students to find out the level of student knowledge about the COVID-19. Most students with special needs can understand COVID-19 through education and getting information from their environment. They understand COVID-19 through habituation, appropriate methods, and media, as well as simple and concrete explanations.

Keywords: COVID-19, education, information, knowledge, students with special needs

1. INTRODUCTION

COVID-19 stands for Coronavirus Diseases 19, and this pandemic was first discovered in 2019 (Ana 2020, 246-260). At the time this research conducted, Indonesia is experiencing problems because COVID-19 outbreak has hit people in Indonesia. Patients infected by COVID-19 in Indonesia continue to grow (Martina et al. 2020). We need efforts to prevent the spread of COVID-19. Giving education and information about COVID-19 is very important to students, especially for students with special needs. Students with special needs are students who have problems in both developmental and academic aspects. They need teaching, guidance, and special services. Students with special needs have difficulties in understanding information (Maryanti et al. 2020). They need methods and media that suit their needs. Students with special needs have difficulties understanding abstract phenomena (Maryanti et al. 2020, 1909-1920). They need concrete media to understand.

COVID-19 is a virus that can infect the human body. This virus has a very small size and invisible (Maryanti et al. 2020). We need an electron microscope to observe this virus. The small form of the virus makes it easy for viruses to enter the human body (Li et al. 2020). For students with special needs having knowledge of COVID-19 is very important. They have a greater potential for being infected with the COVID-19 virus compared to normal students. That is because they have a weak immune system, low awareness of hygiene (Giust and Valle Riestra 2017), and limited knowledge about the dangers of COVID-19.

At present, there are many papers or news that contain information (Hashim et al. 2020), the form (Sahin et al. 2020), the size (Yunus and Rezki 2020), the transmission (Windhiyana 2020), symptoms (Razon 2020), the impact (Putra and Abidin 2020), and the efforts to prevent the COVID-19 (Telaumbanua 2020). However, until now there has been no paper or book that explains education and information about COVID-19 knowledge for students with special needs.

Students with special needs can get education and information from their environment (Kurniawan 2017). Education and information about the COVID-19 are not only obtained through education from teachers in the formal environment. However, students can obtain education and information from the family and the community. Students understand information through habituation, appropriate methods, and media, as well as simple and concrete explanations. This study was one of the efforts to prevent the spread of the COVID-19 in Indonesia.

2. THEORY

COVID-19

The COVID-19 is a virus originated from animals (Maryanti et al. 2020). This virus first spreads in the city of Wuhan, China. The virus can infect the human body through the nose, mouth, and eyes, causing shortness of breath as it damages the lung organs. This virus is very dangerous and even causing death (Angraeni et al. 2020).

The small size of the virus makes it easy to enter the human body (Hamidah et al. 2020). We can prevent the spread of this virus in several ways, including keeping a distance,

maintaining the cleanliness of the body, washing hands, and wearing a mask when leaving the house. COVID-19 pandemic does not only affect public health problems but also economic, social, and educational fields, especially in Indonesia.

Students with Special Needs in Indonesia

Students with special needs are students who have problems in their developments and it affects their academic performance (Hermawan et al. 2020). There are several categories of students with special needs including visual impairment, hearing impairment, intellectual disabilities, physical impairment, autism, and down syndrome. The classifications are simply explained as follows:

- 1) Students with visual impairments known as blind people are students who have problems in their visual senses (Purwati et al. 2020).
- 2) Students with hearing impairments have problems with hearing organs or nerves resulting in hearing disability (Hidayat et al. 2020). They usually have difficulties in understanding and communicating verbally.
- 3) Students with intellectual disabilities are often referred to mentally disabled (Sari and Kustiawan 2020). They have below-average intelligence, problems in adaptive behavior, and independence.
- 4) Students with physical disabilities in Indonesia are called *tunadaksa* (Munir and Aljauhari 2020). Students with physical disabilities have problems in their physical aspects, one of which relates to gross and fine motor movements.
- 5) Students with autism are students who have problems with interaction and communication (Ayunungtyas et al. 2020). They have difficulties in establishing eye contact and communicating their needs.
- 6) Students with down syndrome are students who have the same facial characteristics, short thick tongue, and short fingers (Keen et al. 2020). They have problems in the aspect of intelligence, usually included in the classification of mentally retarded children.

Education for Students with Special Needs

Education for children with special needs is different with the education in general (Hernawati 2007). Educating children with special needs requires special methods, strategies, media, and services based on their needs that impacted by their conditions. There are several principles of educational services that must be considered in an effort to educate children with special needs such as compassion, individual service, readiness, advocacy, motivation, learning, working in groups, skills, and the cultivation and refinement of attitudes (Abdullah 2017).

3. METHOD

This research used descriptive qualitative method. The subjects in this study were students with special needs (visually impaired, deaf, intellectually impaired, physically impaired, autistic, down syndrome) in special schools in Indonesia. We obtained data through a number of questions given to students. The aim was to determine the level of students' understanding of the COVID-19. We made 15 polar questions, and the analysis of a score of 0 (no) and 1 (yes) with a total score of 100 for all questions answered with 'yes'. We made questions through Google Form and distributed the questions through social media. Parents and teachers played an important role in helping the process of obtaining data in the field. Table 1 shows the 15 polar questions given to students.

4. STUDENTS DEMOGRAPHIC

Figure 1 displays student data about the types of challenges they encountered. 7% of students were students with visual impairments. Students had obstacles in orientation and mobility, understanding abstracts, and auditory learning. 18% of students had hearing impairments resulting challenges in language, speech, and communication. They also had visual learning characteristics and difficulties in socializing and behaving. Furthermore, 45% of students were children with intellectual disabilities. They had problems with concentration, adaptive behavior, and intelligence. Students with intellectual disabilities generally are easy to forget, easily bored, difficult to focus, difficult to understand abstract concepts, and problems in independence. 8% of students were children with physical disabilities. They had problems in the perception of motion, gross motor, and fine motor.

Table 1. COVID-19 knowledge question instrument for students with special needs

No	List of questions	Answer	
		Yes	No
1	Do you know what COVID-19 is?		
2	Do you know the size of the COVID-19?		
3	Do you know the form of the COVID-19?		
4	Do you know that the COVID-19 originated from animals?		
5	Do you know how the COVID-19 is transmitted?		
6	Do you know how COVID-19 enters the human body?		
7	Do you know the symptoms of COVID-19 infection?		
8	Do you know the danger of the COVID-19?		
9	Are you aware of the efforts to prevent the transmission of the COVID-19?		
10	Do you know that physical distancing can prevent COVID-19 transmission?		
11	Do you know that washing your hands can prevent COVID-19 transmission?		
12	Do you know that social distancing can prevent COVID-19 transmission?		
13	Do you know that wearing a mask can prevent COVID-19 transmission?		
14	Do you get information about the COVID-19 from your parents?		
15	Do you get information about the COVID-19 from the teacher?		

Figure 1. Types of Disabilities that Subjects have.

In the cognitive aspect, some of students did not experience obstacles and were able to participate in learning like children in general. 12% of students were students with autism who had obstacles in interaction and communication. They had difficulties in making eye contact, interacting, and often raging. 10% of students were students with down syndrome. Students with down syndrome have characteristics of unclear pronunciation, thick short tongue, and fingers, motor resistance, lack of concentration, and have below-average intelligence.

5. EDUCATIONAL PROCESS AND PROVISION OF INFORMATION ABOUT COVID-19 FOR STUDENTS WITH SPECIAL NEEDS

For students with special needs, it is very important to obtain education and information about COVID-19 and how it is transmitted because they have difficulties when studying the COVID-19 (Maryanti et al. 2020). Providing education and information about the virus for students with special needs can increase their knowledge.

In providing knowledge and support, we must pay attention to many issues including students' challenges, the opportunities, and students' needs. They have difficulties in understanding complicated and abstract concepts. As for students with visual impairments, they need learning media that can optimize their hearing and tactile capacities. Furthermore, children with hearing impairments need visual learning media and students with intellectual disabilities, autism, and down syndrome need interesting and fun media.

Basically, providing education and information about COVID-19 for students with special needs requires simple explanations and concrete examples. The role of family is also essential to increase students' knowledge. Collaboration between parents, families, teachers, and the community is needed in educating students with special needs. They can learn through habituation in daily life. As they often get education and information about the COVID-19 from the surrounding environment, their level of knowledge will improve (Abdullah 2017). In an effort to find students' improvement in understanding COVID-19, several questions about the virus were given to students with special needs from easy to difficult questions.

6. DATA ANALYSIS

Table 2 shows the percentage data analysis of students knowledge about COVID-19 before and after given education and information. A few students with special needs knew COVID-19. After given information and education, their knowledge increased.

Table 2. Subject knowledge before and after the provision of education and information about COVID-19

No	Subject	Total	Before Providing Education and Information		After Providing Education and Information		COVID-19 Knowledge Enhancement
			K	NK	K	NK	
1	Students with Visual Impairment	7%	2%	5%	5%	2%	3%
2	Students with Hearing Impairment	18%	6%	12%	15%	3%	9%
3	Students with Intellectual Disabilities	45%	10%	35%	30%	15%	20%
4	Students with Physical Impairment	8%	3%	5%	6%	2%	3%
5	Students with Autism	12%	2%	10%	7%	5%	5%
6	Students with Down Syndrome	10%	2%	8%	7%	3%	5%
Percentage Amount		100%	26%	74%	70%	30%	44%

Note: K= know; NK= Not Know

Students with special needs require education and information to improve their knowledge. They get the knowledge and information from their families, teachers, and community. However, a few students with special needs only receive education from one party. This is one of the reasons why the level of student understanding is low. Environmental factors greatly affect students' knowledge improvement besides the obstacles they have. Building good collaboration between various parties to provide education and information will increase the level of student knowledge.

Figure 2 explains the percentage of efforts made by parents and teachers in providing education and information about COVID-19. About 35% of parents and 65% of teachers gave education about COVID-19 to students with special needs.

Students with special needs are also vulnerable towards COVID-19. Most of them have low self-development skills (rarely washing hands, weak immune system, and poor hygiene). The education and information provided must be adjusted to their needs and conditions. Habituation, simple explanations, and concrete examples help students to understand education and information about the COVID-19. The balanced participation among parents and teachers makes students' knowledge increase.

Figure 2. Efforts made in providing education and information about COVID-19.

CONCLUSION

Providing information and education about the COVID-19 is essential to students with special needs in Indonesia. It is important because students with special needs are very much easily infected by the COVID-19. They need education and information about the virus so their knowledge increases. They can get education and information about the virus from the family, school, and community. 70% of students with special needs can understand COVID-19 through education and information they get from their environment. They understand the concepts through habituation, appropriate methods and media, simple explanations, and concrete examples.

ACKNOWLEDGMENTS

We would like to acknowledge Sekolah Pasca Sarjana Universitas Pendidikan Indonesia for supporting this research. This study was supported by Bangdos Universitas Pendidikan Indonesia. We would also like to thank teachers at Sekolah Luar Biasa in Indonesia for assisting this study.

Chapter 429

INCREASING THE SCIENCE PROCESS SKILLS USING VIRTUAL SCIENCE LABORATORY DURING THE COVID-19 PANDEMIC

Ida Hamidah

Universitas Pendidikan Indonesia, Bandung, Indonesia

ABSTRACT

One of the science learning's main goals is to provide students with skills in the science process. Typically, these skills are acquired when students do an experiment in the laboratory. However, laboratory experiments have become difficult to conduct in the current corona virus disease 2019 (COVID-19) pandemic. This study aimed to examine all forms of learning that could be applied to improve the science process skills of the students. Types of learning that could be performed for this purpose include virtual science laboratory, problem-based gaming, open-ended science experiment, mobile scientific inquiry, and project-based learning. Based on the characteristics of each learning, it is suggested that the most effective learning during this pandemic is virtual science laboratory. This learning has features that offer students the ability to analyze, describe, anticipate, collect, prepare and answer questions.

Keywords: COVID-19 pandemic, science process skills, virtual science laboratory, problem-based gaming, open-ended science experiment, mobile scientific inquiry, project-based learning

1. INTRODUCTION

The corona virus disease 2019 (COVID-19) pandemic has now spread across the world since it first emerged in Wuhan, China in December 2019 (Hamidah, Sriyono, and Hudha 2020). On 11 February 2020, the WHO named the disease as “COVID-19,” an acronym of “coronavirus disease 2019” (Razon 2020). This pandemic naturally affects all sectors of

human life, from the manufacturing, health, transport, government, maritime affairs, to education (Ng and Peggy 2020). Education plays a key role in shaping people into being resilient people to face the changing challenges of real life. By education, we will prepare students to have certain skills that are aligned with the demands of the workforce. Scientific process skills are one of the skills they need.

Scientific process skills are skills that allow students to observe, explain, predict, pose questions, plan, and communicate (Harlen 1999). Typically, these skills are incorporated into the curriculum when performing laboratory experiments. Students are divided into different groups, then work together to accomplish an experiment with a particular topic, discuss data analysis and report results. It can be identified that there are additional benefits to the students during the experimental activities. Students feel inspired and enjoy doing it, because these practices help students grasp a concept in the same way as a scientist discovers the theory (Elfeky, Masadeh and Elbyaly 2020). Unfortunately, this practice could not be performed during this pandemic because almost all countries implement lockdown to prevent wider spread of coronavirus. The implementation of quarantine is also supported by the findings of scientists by conducting analysis based on Reduced-Space Gaussian Process Regression, which states that new quarantine measures with more restrictions for the implemented containment strategy can be successful, but in a late period (Arias Velásquez and Mejía Lara 2020).

However, learning must continue. There is no way we can let students go through the day without a lesson. During this pandemic, various ways can be taken to keep students involved in learning, including virtual science laboratory, problem-based gaming, open-ended science experiment, mobile scientific inquiry, and project-based learning.

Among the learning models listed above, it is prudent for a teacher to be able to choose one that is in line with the characteristics of science learning. In Indonesia, the fourth core competency of the 2013 curriculum notes that students must be able to process, view, and reason in the concrete realm (use, interpret, organize, modify, and make) and the abstract realm (writing, reading, counting, drawing, and composing) according to what is learned from the same perspective or theory in school and other sources (Kemendikbud 2014). These core competencies are consistent with the scientific method, namely the acquisition of knowledge through observation, questioning, testing, reasoning, analysis, presentation and creation, which are carried out in deep discussion or group practice through classical activities.

Acquiring knowledge through practicum group activities will train critical thinking and problem-solving skills as one of the skills of the 21st century. Therefore, there are several ways to improve science process skills. It can be obtained through virtual science laboratory, problem-based gaming, open-ended science experiment, mobile scientific inquiry, and project-based learning.

2. SCIENCE PROCESS SKILLS

Practicum group activities, as described previously, may provide students with skills in the science process. Science process skills are a wide range of transferable skills, applicable for many disciplines and representing the scientists' behavior. Science process skills can be divided into two levels as basic and integrated. Basic science process skills consist of

observation, communication, classification, measuring with numbers, inference, prediction, and using the space-and-time relationship. Integrated process skills consist of interpreting data, controlling variables, defining operationally, making hypotheses, and experimenting. Those two science process skills are essential cognitive skills for the success of primary school science learning, specifically at the pre-school or early childhood level because children do not have sufficient cognitive competence. Therefore, science processing skills for them do not need to be overemphasized. Nonetheless, the teaching of basic skills that will lead them to higher-order skills should also be guided. The active role of students to play, discover, solve problems and conduct research needs to be explored in the learning curriculum developed by the teacher. (Bati, Ertürk and Kaptan 2010).

Experts recommend that each stage be evaluated through a series of questionnaires to ensure the effectiveness of providing students with any measure of science process skills. The questions can include the students' findings related to their initial questions, the comparison to their findings with their earlier predictions, the associations between changes in one variable and another, the patterns or trends against all the evidence, the conclusion that students summarize and also students' recognition that any conclusions may have to be changed in the light of new evidence (Harlen and Jelly 1997; Harlen 1999). To provide science process skills with each indicator, the following describes several learning models or strategies that correspond to its characteristics.

3. VIRTUAL SCIENCE LABORATORY

Initially, the virtual science laboratory was intended to improve students' understanding of science concepts that have abstract phenomena (for example, the concept of electric fields, electricity flow and fluid flow) or to overcome the limitations of experimental equipment in schools that lack complete practical tools. However nowadays, in accordance with the rapid advancement of information and communication technology (ICT), virtual science laboratories can be applied to various subjects outside of science, for example mathematics, engineering, and languages. In general, the virtual science laboratory module must provide various information or instructions before students carry out a science experiment project, namely:

1. Course and content introduction
2. Problem or question introduction
3. Discussion and Collaborative Learning
4. Links to other learning resources and case studies
5. In-house three-dimensional virtual laboratory
6. Online scaffolding (Klentien and Wannasawade 2016)

Virtual science laboratory is a term used to refer to a digital environment designed to meet research needs. A significant contribution to many research domains, facilitating more efficient, open and reproducible research in new ways possible through virtual laboratories (Barker et al., 2019). Specifically, virtual science laboratories refer to integrated access to a variety of resources including software, databases, collaboration tools, workflows,

instrumentation, and high-performance computing, usually via websites and mobile applications. Thus, the virtual science laboratory requires an internet connection when operating it. However, during difficult times like we experiencing nowadays, every virtual science laboratory developer is required to produce programs that can also be accessed offline.

There is a wide variety of applications available on the market for building virtual laboratories, from basic to complex, from free to purchased applications (Bilgehan, et al., 2016). All of this software is useful for producing various kinds of simple simulations to more sophisticated virtual laboratories. The subject matter can be presented to students in an integrated way with its web-based and mobile application-based characteristics. Virtual science laboratories can be used effectively in the classroom as well as outside the classroom, even at home if some further work may be required. What needs to be addressed when developing content in a virtual science laboratory is the pedagogical aspect that is integrated with the content that enables students to construct an easy-to-understand learning environment (Esquembre 2015).

A more sophisticated virtual laboratory model, for example, can be created with unique characteristics into a 3-dimensional interactive virtual laboratory. Due to its design, this model is the first of its kind which allows multi-admin, multi-user, special software compatible to run on iPad, iPhone, android and other smartphone platforms. This 3-dimensional virtual laboratory is ideal for the use of all student-centered active learning models (problem-based learning, cooperative learning, project-based learning, inquiry-based learning, research-based learning, invention-based learning and structuralist learning), due to its multi-user nature and accessible through the Internet (İnce et al., 2015).

Several research findings have shown the acceptance of the virtual science laboratory, including that student acceptance of this technology is focused on levels of performance, enjoyment and student satisfaction. Efficiency and fun are factors that positively influence student adoption of this technology. As a result, virtual activities and practices must be well designed to provide a successful educational environment for students. Additionally, virtual tools should be built with a playful approach, since fun and enjoyment are essential to involve students in the subject matter and learning process, as well as to increase the motivation and acceptance of these tools (Estriegana, Medina-merodio and Barchino 2019).

In contrast to science subjects, in the engineering field, virtual laboratory applications are less meaningful if the students' desired skills are hands-on especially if it is applied to distance or online learning. The reason for this difference lies in the fact that engineering often requires laboratory training to provide effective skill acquisition and hands-on experience. Real laboratory still needs to be activated or replicated as a virtual laboratory that is completely software-based (Potkonjak et al., 2016). In line with the virtual science laboratory, virtual learning is also being promoted in various countries (Almarzooq, Lopes, and Kochar 2020; Jowsey, Foster, Cooper-Ioelu, and Jacobs 2020) because during pandemic like this time, face-to-face learning is less likely to be implemented.

4. PROBLEM BASED-GAMING

Teachers often have to think that learning must be enjoyable for students, so that they can acquire knowledge in a more meaningful way. Games are a medium that can be used for this purpose, like puzzles or simulations. Games could become simple solution games or complex multi-solution paths that require inquiry skill and all dimensions of science process skills to complete. Games are proven to be able to meet the challenges of strategic and logical thinking as well as challenges to win the game (Rahmani and Abbas 2014). Other researchers also mentioned that problem-based gaming can improve student programming skills (Topalli and Cagiltay 2018). This is because problem-based gaming can increase student motivation to introduce programming concepts. In addition, because they can see the big picture of the software development cycle and the place of coding in that cycle, their understanding of programming concepts can most likely be conceptualized thereby enabling them to better integrate other concepts in their programs. Specifically, for increasing learning motivation, the same thing is also revealed that with problem-based gaming in the English course, student learning motivation can be further improved compared to conventional learning. (Hwang et al., 2017).

5. OPEN-ENDED SCIENCE EXPERIMENTS

The open-ended experiments are designed to enable students to explore and create. This method allows students to select experimental equipment, obtain and interpret data, and to determine results. Therefore, with the open experimental method it is hoped that students can develop psychomotor skills and behaviors such as thinking, deciding, making original implementations according to their decisions, and deducing the results obtained (Aydoğdu, Buldur, and Kartal 2013). The results of other studies show that with an open-ended experiment, students are able to better design and carry out experiments, analyze and interpret experimental results and work in groups (Haron et al., 2013). They are also able to design their own procedures, analyze and interpret experimental results, and work in teams (Mahmoud, Hashim and Sunarso 2020).

6. MOBILE SCIENTIFIC INQUIRY

Mobile scientific inquiry is defined as a scientific investigation application that is supported by mobile devices in the science process skills. The development of mobile scientific inquiry is based on the fact that the use of mobile devices has become an integral part of our daily lives, and this has great potential for educational applications. With a storage unit, camera, sensors, and internet connection, it allows students to use their cellphones for more meaningful learning. Regarding science process skills, technology-based inquiry activities need to be designed. Developing better science process skills, which are not only related to science but also with problem solving and critical thinking, will help students to develop higher order thinking skills that can be generalized for the life of students (Ekici and Erdem 2020). Learning using mobile scientific inquiry is also suitable for fostering student

curiosity and motivation. It helps learners to develop their ability to work in complex and unpredictable environments that can make them critical thinkers and agentic learners (Suárez et al., 2018).

7. PROJECT-BASED LEARNING

Project-based learning is a learning that refers to an inquiry-based learning method that involves students in knowledge construction by asking them to complete meaningful projects and develop real-world products (Guo et al., 2020). Project-based learning can also increase student motivation and problem-solving abilities (Chiang and Lee 2016). Through project-based learning, students are trained to challenge driving abilities focus on learning goals, participation in educational activities, collaboration among students, the use of scaffolding technologies, and the creation of tangible artifacts. Of all these measures, the most relevant is the development of tangible objects which can authentically solve the problem. This indicator differentiates project-based learning from other student-centered learning, for example problem-based learning (Helle, Tynjälä and Olkinuora 2006). This creation process requires students to work together to find authentic problem solutions in the process of integrating knowledge, application, and construction. Instructors and community members (clients), usually as facilitators, provide feedback and support for students to help their learning process.

Project-based learning with its indicators is a powerful teaching method that can achieve the following results: (1) motivating students, (2) preparing students for college, careers and becoming good citizens, (3) helping students meet expectations and perform well on tests that allow students to demonstrate knowledge and deep thinking skills, (4) enable teachers to teach in a more satisfying way, and (5) providing opportunities for schools and governments to find new ways to communicate and connect with parents, the community and the wider world (Larmer, Mergendoller, and Boss 2015).

For all the characteristics of each defined model or learning media, teachers are required to be able to sort, select and develop content that is integrated for pedagogical aspects to improve students' skills in the science process. Particularly in the current situation, where face-to - face learning is difficult to do, students need the psychological touch of a teacher that is represented in every learning model or media that teacher develops.

CONCLUSION

Being based on the five learning models or media outlined, the authors argue that the Virtual Science Laboratory is one of the most likely strategies to be implemented to equip science process skills in the current COVID-19 pandemic situation. It is because, in the virtual science laboratory learning, all the necessary experimental stages have been properly incorporated into the module. Then, by utilizing ICT which is very advanced and familiar to students, teachers can further develop learning programs that are in line with the current situation (contextual) and students can also be creative in exploring their environment in the search for scientific concepts like a scientist. Hopefully, everyone's creativity would be

strengthened so that it can produce something useful for all especially during the COVID-19 pandemic which no one expected or want.

ABSTRACT

As the COVID-19 pandemic spread around the world, most educational institutions have been temporarily closed and it affects the student learning process. A competent and skilled teacher is one of the most important inputs in the education system, but teachers are often unprepared for teaching in crisis and post-emergency settings. They are stressed since they cannot attain responsibility as their roles. It seems that some competencies in the 21st century do not efficient enough to the crisis settings. This crisis teaches a lesson to the educator to rethink the teacher efficiency competences. Research claims that a relationship and cooperation with communities for learning organization is the competency that significantly helps student learning in the crisis-affected setting. Moreover, technology literacy is advantaged to help students learning in and out the classroom. Teachers with limited qualified for technology have to be trained. To prepare the new generation student for the fast-changing world and in times of emergency, the teachers should have more efficient and competent. The competent teacher can shape the best student.

INTRODUCTION

COVID -19, an emergency pandemic presents the big experience for the global citizen and all the organizations, including education. There are no schools, no exams, but teachers. The crisis is highlighting the teacher to play the roles outside the school because of the closure of schools. How could they be responsible for this challenging role, outside-school teachers? In Thailand, there are nearly 13 million students, which are out of school and 600,000 teachers are unable to teach in their classes until at least 2020; however, education has to continue as soon as possible through alternative learning pathways (Rattana Lao 2020). Online learning and distance learning program are the responses for teaching and learning within the urgent condition (Saripudin et al., 2020). This means Thailand maintains the learning and ensures that all the students retain knowledge and skills. Although that is just the action in the short term, it causes bitter stress to teachers, students, and even the parents. Not all teachers can use technology to teach. Some of them are just trained whereas the students especially those who are in the rural area are out of necessary technological tools for learning. Worst yet, some parents, who are unemployed during the crisis or have low-wage jobs, have no time to fill in the temporary teachers for their kids nor have the financial resources to afford outside support (John DaSilva 2020). Due to the big impact of the crisis to the education sector around the world, educators have to rethink what the education and teacher competencies for emergency settings in the future should be.

TEACHER COMPETENCIES AND THE STUDENT SUCCESS

Being a teacher at any level requires a significant amount of knowledge and skill. Teachers are key to success in education. The competent and skilled teachers make learning possible whether during times of crisis or not. Research confirms this common perception that all factors under the control of schools, the maximization of student success relates to the powerful influence of teacher the most (Babu and Mendro 2003). The competencies address the ability to do something successfully or efficiently. Competencies are not skills, but competencies are inherent qualities an individual possess – combining skills, knowledge, and ability. What are teacher competencies? They are a combination of skills, knowledge, behavior, and attributes that enable effective or better job performance. To fulfill student learning, teachers must have expertise and good competencies with the changing educational context where hundreds of critical decisions are required (Jakson 1990).

According to the importance of the teacher, paying attention to the competencies for teachers helps to ensure that all teachers are prepared to make school a positive experience for students and their families. The strong set of competencies that every competent teacher also needs to possess are knowledge, skills, and values. What core competencies do the modern effective teachers in the 21st need for preparing their students and equip them with the essential skills required for the future? UNESCO (2011) defines that the teacher competency in 21st Century consisted of five core competencies which are knowing and applying technology; deep understanding education policies, curricula and be updated on national, regional, and global developments, what to teach, assessment, flexibility in teaching, instructional skill for problem-solving; building the knowledge of learning process, learning

strategies, Information and Communication Technology (ICT) instruction, ICT community designing to promote the continuous learning skill; being a leader of the colleagues and community; and developing teacher profession as well as applying ICT for the professional learning community. That is the big picture of teacher competencies in the global level. Similarly, in the Southeast Asia region, the eleven Ministries of Education realize that schools today operate in a complex and constantly changing world of knowledge and information. Thus, the Teachers' Council of Thailand (TCT), in partnership with the SEAMEO Secretariat (SEAMES) and the SEAMEO Regional Center for Educational Innovation and Technology (SEAMEO INNOTECH), initiated the development of the Southeast Asia Teacher Competency Framework (SEA-TCF) in April 2017. The SEA-TCF consists of four essential competencies and twelve general competencies that high performing teachers in the region must possess. Four essential competencies are:

1. Know and understand what to teach. This is the ability of teachers to deepen and broaden their knowledge on what to teach, understand education trends, policies, and curricula and be updated on local, national, regional, and global developments.
2. Help students learn. It is the ability to know their students, use the most effective teaching and learning strategy and assess and give feedback on how students learn.
3. Engage the community. This is the ability to partner with parents and caregivers, involve the community to help students learn, and encourage respect and diversity.
4. Become a better teacher every day. This is the ability to know oneself and others, practice human goodness and then master the teaching practice. (Teacher Council of Thailand 2018).

However, the competencies listed in the framework can be interpreted based on local context and specific needs. For Thailand, the teacher competencies included five core competencies and six functional competencies. The core competencies consisted of an achievement in performance, self-development, teamwork, ethics, and teacher profession conducts, while the functional competence consisted of a curricular administration and learning management, a learner development, a classroom organization, an analysis, synthesis, and research for a learner development, a teacher leadership, a relationship and cooperation with communities for learning organization (Chatchai Wangmeechongmee 2017). It seems that the competencies defined are able to enhance the student 21st Century skills - learning skills, literacy skills, and life skills, but some are inadequate for the emergency setting.

WHAT KIND TEACHER COMPETENCY IN POST- CRISIS?

In this crisis situation, the risk-control decision of government led the students to study at home with the distance learning program or online learning. This causes a degree of inconvenience and problem. Students lack technology tools. Although they are the digital age citizen, they cannot learn. Besides, some cannot access the online system. Some teachers and parents lack of technology implementation potential and problem-solving skills. To provide technology to support the students learning opportunity and to imply technology to enhance

students' knowledge, learning is essential for the 21st Century teachers. In fact, some teachers cannot operate a computer as well. Because of the sudden COVID-19 crisis, the educators evidently perceive that teacher is incompetent in technology. The question is if the others are efficient enough for the current rapidly changing world, especially in the emergency setting.

To continue the student learning during the crisis, the educators have to emphasize on the access to learning and the quality of education as well. There is a strong evidence supported that the use of community-based education is the valuable channel to increase access to education, including accelerated learning programs, and approaches to distance learning for primary, and secondary students. For the quality of education, community-based education and community participant monitoring are needed to increase academic achievement for the primary school students related to one of the 21st century competencies (Burde et al., 2015), as well as a relationship and cooperation with communities for the learning organization. Therefore, to build a strong relationship with the community, one success key is to make strong education. Besides the community supporting, remote education in the midst crisis is the other success key.

Digital learning television, online learning, and distance learning program are the alternative nation educational pathways. Although learning through TV is user-friendly and particularly for vulnerable students, it is a one-way communication. Online learning is "the most ideal" for the current situation in Thailand because of its ability to accommodate a two-way communication and a real-time response, so digital literacy competence is also essential for the teacher in this crisis (Kertbundit 2020) UNESCO defines that knowing and applying technology is one of the 21st-century competence; nevertheless, some teachers are still inadequate in this competency. How are about students? They will be no problem for the digital age generation, but some families do not either have access to the same technology tools (internet, computer, television, smartphone) nor have the same level of knowledge and skills in using technology. It is impossible for online learning. It is crucial for the teacher to follow up and identify the specific needs of the vulnerable students to maintain their appropriate learning which reflects that learning management and learner development are also practical competencies.

The spread of COVID-19 is the great opportunity to reform the education system, including the teacher profession development (Sangsawang 2020). What should the competent teacher in post- crisis setting be? Are the teacher competencies today sufficient for tomorrow world? As the responsibility in shaping the students and community, development of the competent and skilled teachers is the most considering factor. Unfortunately, the professional teacher development in Thailand is not as successful as the expectation level. One way to develop the effective professional teacher is to develop teacher competency. Undoubtedly, there are some 21st Century teacher competencies are relevant to the research finding competence in crisis: a relationship and cooperation with communities for learning organization, learning management and technology literacy.

Right now, the educators have to learn that both pre-service teacher and in-service teachers have to be retrained some essential competencies to be more effective, especially technology literacy. Not only those competencies in 21st century are the emergency response but also some renew ones. The recently crisis teaches the educator a new lesson for preparing the better students for what the future might hold. The lessons are to educate citizens in an interconnected world, redefining the role of the educator, teaching life skill needed for the future, and unlocking technology to deliver education. Similarity, some researchers (Helen

Soulé and others (2014)) stated their researches that project based and inquiry-based learning (PBL) instructional 21st century learning practices is proven to produce positive student outcomes. They also claim that “PBL and other instructional practices that promote student engagement, real-world experiences, the acquisition of 21st-century skills, and transform the role of the teacher from lecturer to guide/facilitator have been shown to produce the desired student outcomes (Soulé, et al., 2014, <https://www.hanoverresearch.com/insights-blog/bringing-21st-century-skill-development-to-the-forefront-of-k-12-education/>, retrieved on July 1, 2020).” According to the research, the practical instructions reflect a very different role for teachers and require significant changes in behavior, pedagogy, and practice. The significant competence for the unpredicted future, emergency setting should be:

1. Pedagogy competency, including ability to design learner centered methodology, organize instructional management related to the learner requirement, the contexts, and the situations (Mulyanti et al., 2020, 271-282).
2. Flexibility and adaptability competency, including the ability to adjust profession planned work by gathering relevant information and applying critical thinking to address multiple demands and necessary priorities in a changing environment and emergency setting.
3. Social competency, including the ability to deal with social condition, get more sensitive to the problem around, access to the society well, take another’s perspective, or idea concerning a situation.
4. Critical decision competency, including the ability to critical analyze the education situations and problems, as well as to make a critical decision to solve the conflict and problem based on the information analyzed in specific context.
5. Lifelong learning competency, including the ability to gain knowledge and skills continuously to develop professional job, and to provide quality learning.

The teacher is the most important factor indicating the quality of education; therefore, they need strong and efficient professional competencies. COVID-19 is the catalyst to reform the education system and the teacher competency in managing the quality outcome, so teachers’ competencies must be reviewed and redefined depending on the fast-changing world and the unexpected crisis (Ana 2020). A relationship and cooperation with communities for learning organization the competency related to the research findings, showing that community-based education and community participant monitoring are increasing academic achievements for the primary school students related to one of the 21st-century competencies (Burde et al 2015). The competent teachers are the ones who can collaborate well with the community in order to build a learning organization. This is necessary for the crisis setting for the closure school and students have to study at home. Some parents have no time and lack of knowledge and digital skill which put them a lot of pressure. The teachers collaborate with the community to continue student learning it reflect the teacher’s proficiency in learning management. In addition, the alternative pathway in the pandemic is online learning and distance learning. Online learning is “the most ideal” for the emergency situation in Thailand, the interrupted education could be progress if the teachers and parents are potential resources.

The educators have to rethink what the other necessary competencies are required for the fast-changing global. The responses are pedagogy competency, flexibility and adaptability

competency, social competency, critical decision competency, and lifelong learning competency. As the education needs a competent teacher, the professional development (both pre-service teachers and the in-service teacher) must be a priority and carefully prepared in order to shape the best teacher that they can be. To support the success of the student, government initiatives to maintain student learning cannot be effective without the use of an invaluable educational resource.

CONCLUSION

A competent and skilled teacher is one of the most important inputs in the education system, but teachers are often unprepared for teaching in crisis and post-emergency settings. This crisis teaches a lesson to the educator to rethink the teacher efficiency competences. The relationship and cooperation with communities for learning organization is the competency that significantly helps student learning in the crisis-affected setting and technology literacy is also advantaged to help students learning in and out the classroom. Teachers with limited qualified for technology have to be trained to prepare the new generation students for the fast-changing world and in times of emergency.

ABSTRACT

The COVID-19 outbreak has caused a big problem for Thai students and parents because most of the education systems have not yet entered the world of learning. By using program for International Student Assessment digital devices, the data showed that teachers and schools are well-equipped with technology and support online teaching. In the aspect of students' access to the internet, Thailand still has students who are in unfortunate and unfavourable environment. Qualified online knowledge is essential and various fundamentals should be taken into account in order to ensure that all Thai students receive quality learning. The COVID-19 Adult Digital Technology helps students to acquire quality knowledge. However, it is a costly education learning system and paying special attention to the suitability of applications that maintain the relationships of teachers and students, including family members' relationships is needed.

Keywords: COVID-19, crisis problems, Thai parents' perspectives

INTRODUCTION

The advent of the COVID-19 crisis reveals that most education systems have not been ready to enter the world of learning using digital devices. Based on the data collected from 15-year-old students and school administrators at Program for International Student Assessment (PISA) 2018 in 79 educational systems around the world, it was found that many

opportunities and access to online learning begin with the basic necessities of online learning. Having a quiet place is the first thing that students should have in order to concentrate on learning. PISA 2018 found that only 15% of students in Organization for Economic Cooperation and Development (OECD) countries do not have a quiet place in their home to use for learning and up to 30% in Indonesia, the Philippines and Thailand (Boonsu, 2020).

In Thailand, there are students who come from schools with inferior socioeconomic status, reporting that there are no more quiet places in the house for learning than students from schools with socioeconomic status who obviously have a distinct advantage. In Thailand, important information from PISA 2018 shows that Thai students still lack important factors for online learning at home, including quiet places in the house for computer learning and internet connection. A comparison between students from disadvantaged schools and students from advantageous schools including Thailand shows the gap of having computers at home between these two groups is more than 50%, which shows the inequality of educational opportunities. Furthermore, Thailand has about 80% of students accessing the internet from home, in which the difference between students from advantageous schools and students from disadvantaged schools is approximately 30% (Institute for the Promotion of Teaching Science and Technology 2020; OECD 2020; OECD 2020b).

Thai Parents' Opinion on the Student Studying Problems

The situation of the COVID-19 outbreak affects the teaching and learning of Thai students who have to study online. However, the readiness and family status are different. Some families may be in a position to have everything, and some parents are able to access the learning media when needed, whereas other families may not be able to afford it at all and it is a huge issue that affects them. During the outbreak, students should study at home in online learning. It means the learning must be compatible with the Wi-Fi contract system including communication devices such as computers, laptops, and tablets that can be used to efficiently access the online program. Besides, the place for studying and sending the assignments to their teacher or lecturer must be a private space or a quiet room such as private bedrooms. Another problem for a university student where the student requires to follow real time online class so the student has the responsibility to a certain extent. However, in a primary or secondary school student's case, there must be a guardian to monitor them especially primary school students. They need close guardians to help them in their learning. As some comments from Thai families are as follows:

"...Since our family has two members who are students in a university and junior high school the effects found are different. In March, when the COVID-19 outbreak began in Thailand, it has impacted the exam study, which was close to the end of the semester. The government has encouraged schools to accelerate the learning and give tests faster and stop learning once the exam is completed. The regulation did not give much impact to primary and secondary schools because the school holiday is closer. However, for the student studying at the university level the student still needs lecture, therefore, the learning has changed to teaching and testing online because the student is an English language student. It is still a mid-term study and will continue to study and have exam. This may cause problems in online learning because either students or teachers have never had this type of teaching before and are not ready. The problem occurs as well as adaptation for online learning at home or on the internet via wi-fi using a laptop or tablet should also be taken. Our family is ready to promote necessary learning media equipment and support the arrangement of the health care readiness in our area, useful food discussions for encouragement..."(Taipae 2020).

"... As a parent, I wish the director of every school and the Ministry of Education help to review the teaching online learning as well. As I see the hardships of many parents and they have come to discuss to share our varied challenges and the reasons behind them. Therefore I would like to give examples below:

- 1 *In order to have online learning, it is very important for students to have a computer and internet connection. If they do not have those facilities at home, they cannot learn. Consequently, parents have to buy them in order to support the children learning but computer is quite expensive. On the other hand, at this time, parents have less work and make a living is difficult, find extra money is challenging and it is also difficult for to find money for food or buy a daily. If a family has two or three children, they have buy two or three devices because the children must study online at the same time. Some parents do not want their children to be inferior to others. As a result, parents must borrow money to buy computers so their children can learn like other students. Moreover, they must find money to pay for tuition, books, clothes, school supplies in each semester and it has already been difficult. Why should we find more money to pay for the computer?*
- 2 *Regarding online learning, if there are no adults sitting near children, do you think the children will not open other pages like YouTube, games, and other websites? Will each student study hard? And if the parents have to sit and watch over the course, when will they work to pay for the newly purchased computer?*
- 3 *For young children, such as kindergarten 1-3, is it appropriate to allow children to sit and study in front of the screen for such a long time? It affects their eyesight and also they do not have long attention span to endure sitting and listening until the class over.*
- 4 *Parents must pay tuition, but they must sit and teach all of their children. The point is why parents would pay the tuition if parents must sit and teach children. Paying tuition does not mean we will teach our children or we cannot raise children. During the online learning, the schools do not lower the tuition but still pay the same amount of tuition. And if parents have many children, the parents may not be able to take care of all the children's learning, because they study online at the same time.*
- 5 *If parents do not let the children study online for their own reasons, will children be embarrassed? When they are embarrassed, as a result children do not want to go to school the next day, suppressing various things and children will ask parents to buy a computer that every child wants. However, many students, instead of studying they play games or see the movies. Do you think most kids will do what more than each other?*

Therefore, for the aforementioned reasons, I would like to ask the director of every school and the Ministry of Education consider them as well because I think it affects parents in many ways, and these are just some examples to understand. There are still many reasons that impact how hard parents have to fight with the online education policies you have created now". (Boonsuk 2020)

Problems in online learning have also been encountered by university students since March 2020. Initially, the modifications on the learning made quite suddenly causing students and professors had not much time to prepare or adjust. It has causes problems that emerged both from teachers and students. Some teachers are old who lack information and technology skills, creating difficulties with the use of programs and instructional materials when they conduct online courses. It takes time to solve the problem or call someone to help and it takes almost an hour of study time (Mulyanti et al. 2020). Regarding the issues with the study time, as in the past, one subject took three hours but was changed to just two hours.

Other challenges include difficulties in understanding the content and learning styles, questions and also answers are not clear and distinct from the classroom. The instructors sometimes let the students study from the recorded clip. Consequently, when they do not understand the lecture, they cannot ask immediately. Additionally when doing groupwork, students encounter problems especially when they need to coordinate with peers specifically when submitting work to the teacher. The fact that students have to present their work online is also difficult (Ana 2020). Students are unable to solve problems as good as while learning in the classroom and most importantly, the problem of inter-connected signals that sometimes gets stuck or fails.

Figure 1. News in television about Thai parents and teachers concern about online study (Television Station Channel 23 2020a; Television Station Channel 23 2020b).

Furthermore, concentration span is also an issue as studying at home is different from studying at school (Sangsawang 2020). At home, other family members accidentally might disturb the student. Students commented that online learning was not as effective as studying in a classroom which was more understandable and merrier. During the online learning, some parents are willing to accommodate the learning and help solve the problem, while some families are willing to provide the tools needed for the learning. However, there are still many families who are not able to support students at all (*Figure 1*).

New semester and opening of schools and universities in Thailand arrive in July. The government announced the semester would be started, however, there is a requirement for educational institutions to manage online teaching along with studying at school by alternating days to study online. Most teachers and parents agree that for elementary and junior high school students studying online for 2-3 are plausible because this group of students still have fairly limited self-control. During school hours, parents should closely monitor the students to help them particularly on certain sections that they do not understand.

Furthermore, students may not have a lot of concentration studying outside classroom because they have never previously encountered this situation. Students may think of their peers, wonder when they could meet in school again, and think of when they start school. This condition affects the students' development. During the online study the family member who would take care of the students would then help to make the learning more efficient.

Online education requires a lot of adaptation from parents and students because each family prepares differently. Most people in Thailand are relatively in the middle level although there are still many people who are in low economic level. Thus, many families will encounter a variety of obstacles in online education. Opinions from some of the parents are:

1. Each family may have two to three children who are at the school age and does not have enough money. Each child studying at different levels, causing problems such as a place to learn at home and insufficient equipment for learning.
2. There are serious problems if a family has children in kindergarten and elementary school years. It means adults or parents should always help and closely control all the time.
3. Parents mostly have to work. Some parents have their own business while others work in public or private agencies. They may not have time to look after children and some poor families will get more problems.
4. Some families do not live with their parents and some live with grandparents or elderly people. If they have to support children education, this is very complicated because some people do not know much about education or uneducated.
5. Families will have to spend more in school supplies if they have more than one child and they will have to pay more for the monthly internet charge that allows the fast Wi-Fi signal speed that helps students to learn well.
6. Education for children is not as effective as studying in school because children may not be concentrated for a long time and lack of motivation because the learning is different from the class in the real classroom.
7. Children will become bored because it is not as fun as studying with friends in the class that has the interactive talk and have fun activities together.
8. Some students may not attend classes online at the time the teacher teaches. It can definitely happen or some students are addicted to games and the might play games instead of studying when their guardian or parents are not around.

The aforementioned are just some of the problems that many families have encountered and they are still worried. Therefore, coping with what has been happening and working on the adjustment together with the parents and students are essential. According to us, below are things that parents might need to prepare:

1. A place to study which is private and no noise, such as a children's bedroom.
2. Sufficient educational materials and equipment at least for two children in order to minimize the educational hurdles they might encounter and they can send the assignments punctually.
3. Schedule for children such as when to wake up take a shower, eat, and study online.
4. Studying time and understand the each course hour together with the children, as well as taking care of learning activities with teachers and friends while online.
5. Monitoring children homework, lesson review and others.
6. Providing children with relaxation from studying to avoid excessive tension.
7. Discussions and communication between parents and class teachers or subject teachers about various problems.
8. Allocating time to take care of the children, although parents are not sure how much they can do.

CONCLUSION

The COVID-19 outbreak has caused a big problem for Thai students and parents because the education mostly served through online classes. In the aspect of students' access to the internet, Thailand still has students who are in unfortunate and unfavourable environment. Online learning is a costly education learning system. Therefore, paying special attention to the suitability of applications (that maintain the relationships of teachers and students, including family members' relationships) is needed in order to provide continuous learning for our students and expand the home school collaboration.

ABSTRACT

Coronavirus disease 2019 (COVID-19) is a new deathly contagious disease that poses tremendous threats to the human race. It was announced by the World Health Organization as a global pandemic. The spread of the virus is the urgent crisis which affects the educational management in Thailand and around the world both in a direct and indirect way. This is considered a big challenge for the opportunity to develop new learning channels and blend online materials or digital technology devices with various instruction in order to broaden the teaching and learning experience on both offline and online platforms so that learners are able to learn continuously, effectively, and efficiently. In Thailand, On Site, On Air, and Online are the keys for every student, either who is able or unable to access online learning, to be able to keep up with the study during the implementation of the semi-lockdown and social distancing measures for preventing the spread of the pandemic by encouraging people, and to limit travel and refrain from participating in activities that involve a lot of people. Regarding this condition, what needed to be taken into consideration is educational inequality, resource management, readiness and cooperation of parents and family, the adaptation of teachers, and changing behaviors of learners. It is required that a strategic plan on educational management must be implemented in order to draw up short-term, medium-term, and

* Corresponding Author's Email: sujinnukaew@gmail.com.

long-term respond plans as well as seek cooperation from various sectors: educational, governmental, and private to support, develop, and exchange instruments or new techniques for successfully overcoming the obstacles of teaching and learning during the COVID-19 pandemic.

Keywords: COVID-19, learning management, Thai students

INTRODUCTION

In the history of Thailand's education, there have always been problems since the founding of Thailand 800 years ago. The first Thai alphabet was invented to protect the nation from losing territories to neighboring states that had already owned a written language (Office of the Education Council. Ministry of Education 2017). Until today when a large number of crises emerged due to different factors such as those relating to public health, the economy, politics, society and Thailand once again works on the crises.

The spread of the Corona Virus Disease 2019 (COVID-19) pandemic has posed a series of impacts to people involved in Thailand's educational sector, ranging from students, parents, teachers, as well as the state and future educational management. COVID-19 pandemic is a serious issue, and combating viral diseases has always been a serious challenge for many aspects, including health authorities throughout the world (Mulyanti, Purnama and Parwinanto 2020).

This COVID-19 pandemic seems to "disrupt" Thailand's instructional management since Thailand's education system has been driven mainly by schools and universities through educational intervention, interaction, and cooperation. In fact, those who are responsible for and play a role in Thailand's education have tried so hard to seek appropriate approaches to move the education system forward.

This is considered the opportunity that lies in the crisis which transforms the education system into a new form, especially the application of "technology" to the instructional system to a greater extent as identified in the Strategy for Promoting and Developing Digital Technology Systems for Education of the 12th National Education Plan (2017 – 2036), which aims at providing Thai people with the opportunity for continuous learning through information technology throughout life. This corresponds to the development in terms of access to equal and efficient services (Office of the Permanent Secretary Ministry of Education 2016). The blending of "technology" with teaching and learning enables the system to run continuously and allows both learners and teachers to access education regardless of places or locations as shown by the analysis of Jeanne Allen, the founder and CEO of The Center for Education Reform, in *Forbes* indicating that there is always opportunity lying in the midst every crisis.

OPPORTUNITY IN THE CRISIS: EDUCATIONAL TRANSFORMATION

Based on the aforementioned challenges and opportunity, information technology is considered the tool for improving and driving Thailand's education forward. The application

of “Educational Technology” to teaching and learning allows learners who are encouraged to keep learning at home during the COVID-19 pandemic be able to keep up with lessons. As for Thailand Minister of Education, Nataphol Teepsuwan, has proposed three plans for basic education teaching and learning management as follows:

1. On Site refers to the normal operations of schools based on the discretion of public health agencies.
2. On Air refers to the teaching and learning approach applied in case schools cannot return to normal operations and the social distancing measure is still implemented. This can be carried out by different means; including Distance Education which are conducted through Distance Learning Television (DLTV), Distance Learning Information Technology (DLIT).
3. Online is the teaching and learning approach applied in case schools cannot return to normal operations as mentioned in point 2 above. Therefore, the teaching and learning activities are carried out by connecting DEEP (Digital Education Excellence Platform) with other platforms such as Google Slide, Google Docs, Google Sheets, Google Jamboard, or Microsoft Teams in which many features such as Chat, Hub, and Microsoft Office are used. In regard to this, the systems proposed in point 2 and 3 above require a test before the next academic semester starts (OBEC Chanel 2020; Silpakorn University 2012).

Generally, there are two parts to online instructional management. First, to which a lot of technologies are applied on which the implementation of the channel currently known as “Live Streaming” which engages teachers and learners in real-time activities as seen in Figures 1 and 2; and synchronous learning which is based on time conditions, teaching (learning schedules), the volume of learning content, and direct transference of knowledge from teachers through technology according to the established curriculum framework. This can be conducted using Facebook Live or Zoom Meeting application.

Figure 1. Live Streaming for teaching and learning.

Figure 2. e-Books are education media on learning platform.

Second, the Asynchronous Learning Network (ALN) can also be used to enable the teaching and learning anywhere and anytime based on learners' needs with teachers to provide on-demand consultation. Through ALN (Figure 3) teachers who are accustomed to the conventional teaching approach may also take on other roles in the education system, such as mentors, counselors, and curriculum counselors. In addition, the content will be posted on media or sent to learners through various platforms, allowing learners to manage the amount of content and then be able to make choices about new knowledge information whenever they want. However, both teachers and learners need to keep up with each other through the use of blogs and social media, such as MOOC, COURSERA, OpenLearnsip (Silpakorn University 2012).

As for higher education (Higher Education, Science, Research and Innovation 2020) instructional management, a lot of precautionary measures against the COVID-19 pandemic have been implemented with the aim of reducing the spread of the virus by encouraging people to limit travel and refrain from participating in the activities that involve a large number of people. There are three practices which are related to higher education teaching and learning management introduced as follows:

1. Stop all forms of teaching and learning activities except those conducted across online platforms. It aims to complete the transition of formal education into 100 percent online learning before 1 April 2020. As for some programs that require the assignments to be completed through practices and operations, each higher educational institution can use discretion to take a careful look for appropriate approaches that encourage learners to spend as much time as possible at home as approved and considered acceptable by the president of each higher educational institution.

2. Consider canceling, postponing, or replacing all kinds of internships with more appropriate activities.
3. Adjust or replace the normal examination and assessment practices with a more efficient one that is appropriate for the online teaching and learning style created.

Figure 3. Teaching recording to provide content to students by asynchronous learning platform.

The management of education could not perform without teachers and students engaged in teaching and learning a certain subject, as its vital elements. Educational innovations can be implemented in instructional management based on the conditions of each particular process or in a mixed form that supports durations, opportunities, conditions, variables, readiness, or the ability to access learning sources primarily available in both classroom approaches or other teaching and learning methods.

Taking into account the acceptance of educational technology among stakeholders at basic education and higher education level, it is found that teachers, parents and all stakeholders in the basic education sector had to adjust slightly to optimize their application of technology due to various related factors such as parental economic disparity, school size, and technical devices. On the other hand, lecturers in the higher education sector are able to immediately apply the innovation. In conclusion, the university can manage their instruction in the new pathway in a short period. This is in line with the Innovation Decision Process Theory proposed by Roger (Rogers 1995) which stated that this process takes a certain period of time and is composed of the five steps to get through, namely knowledge, persuasion, decision, implementation, and confirmation.

This theory reflects the competence of higher education lecturers and students who may have adequate knowledge, skills, and opportunity to utilize innovations. Consequently, they have a higher level of technology acceptance than basic education teachers. However, every related sector needs to handle education inequality as the primary challenge. It is mostly

caused by economic inequality, particularly the gap between the quality of education in rural and urban areas as shown below (Bangkok Department of Education 2016);

1. In rural and urban areas, school administrators do not have adequate resources to plan facilities and technical tools to serve every student.
2. Most teachers might lack adequate knowledge and skills in technology utilization.
3. The economic inequality makes most parents unable to provide their children with access to technology in general.
4. A lot of students lack technology access opportunity due to economic inequality.

Based on the above-mentioned challenges, if the responsible sectors recognize the importance of using technology that promotes deep and wide-ranging learning, as well as equipping learners with other critical skills that technology can help, it is important to implement the following preparatory steps and instructional guidance during the COVID-19 pandemic:

1. Build an understanding and create educational readiness for school infrastructure and the development of teacher skills, use of technology to support teaching, and learning against every kind of challenges (Ana 2020).
2. Introduce guidelines as well as instructional management styles that promote the learners' development of the balance skills in all aspects and emphasize the development of practical skills and other necessary characteristics apart from those related to knowledge development.
3. Develop the required competence of teachers and the ability to connect technology with other approaches to instruction so they can design instructional management styles and provide instructional management then technology can be used as the primary, supplementary, and alternative media. In this context, the media needs to be adjusted and adapted to fit into the schools' context and readiness which take part in creating teachers' learning innovations (Maryanti et al., 2020).
4. Develop learners' competence to support the utilization of technology and promote their Media, Information, and Digital Literacy (MIDL) which is considered the necessarily desired characteristic for learners in the future and a primary factor contributing to the success in online teaching and learning.
5. Adjust and introduce a more flexible curriculum structure and learning areas that are appropriate for the COVID-19 period, and promote the development of the curriculum in which different learning areas are integrated, the loosening of the structure, and the learning approach that prevents and reduces the spread of coronavirus.
6. Use technology to yield educational measurements and assessments with the utmost efficiency. Reflect the actual competence of the learners at a degree equivalent to those measured by an ordinary method of assessment and evaluation, and in the manner suitable for online teaching and learning. This can be conducted through Assessment of Learning (AoL), Assessment for Learning (AfL), and Assessment as Learning (AaL) which cover the precise and assured assessment of all learners' competence.

7. Create a network of cooperation among public and private sectors to support technology-based teaching and learning (Hashim 2020).
8. Build an online Professional Learning Community (PLC), centered on technological usage, in which teachers gather to support each other in order to establish effective teaching and learning strategies for learners during the pandemic by sharing teaching and learning experiences, setting learner goals, evaluating and reflecting each other's personal performance along with teaching and learning consequences.

CONCLUSION

COVID-19 is challenging, however, it creates opportunities for every country to seek guidance for solving and promoting learners to keep up with their education during the pandemic under the friendly, reliable, indiscriminate, and learning-promoting environment. The blending of technology with teaching and learning to the fullest extent within a short period of time leads to new teaching and learning styles that bring about changes in the role of teachers, students, and other educational personnel or even parents. Therefore, the spread of the COVID-19 pandemic has become a valuable lesson to learn, and post-COVID-19 planning must be started so as to prepare the nation for future unexpected threats and risks.

Chapter 433

THE ROLE OF MALAYSIAN SCHOOL ADMINISTRATORS IN FACING MOVEMENT CONTROL ORDER DURING COVID-19

Nazeri Mohammad and Siti Ilyana Mohd Yusof

Department of International Education Cooperation and Relation,
National Institute of Educational Management and Leadership,
Genting Highlands, Malaysia

ABSTRACT

Corona Virus Disease 2019 (COVID-19) crisis may amend our world and our global outlook, it may also teach us about how education needs to change to be able to better prepare our young learners for what the future might hold. As for now, educators around the world are talking about the need to rethink how we can educate future generations. This might just a disruption that the sector needs us to rethink how we educate, and question what to be taught and what are we preparing our students for. Successful people in the coming decades need to be able to understand this interrelatedness and navigate across boundaries to leverage their differences and work in a globally collaborative way. So, as educators grapple with the new ways of communicating with students away from our classrooms, it is a good time to reflect on how this disruptive crisis can help us to define what learning should look like. What changes would need to occur in the preparation of school administrators if the focus of their training shifted to help them more consciously select the lenses that guided their school change efforts.

Keywords: COVID-19, Malaysia, pandemic, school administrator and movement control order

INTRODUCTION

Coronavirus Disease 2019 (COVID-19) has changed how students are educated around the world. Those changes give us a glimpse at how education could change for the better and the worse in the long term (Rodriguez and Rodriguez 2015; Cosner 2014). In fact, the COVID-19 pandemic is fast-forwarding the changes in the scope of the job landscape as predicted by the World Economic Forum (WEF). WEF estimated that 65 percent of children entering primary schools today will end to keep on delivering up working in completely new job types that have yet to exist (Penton and Pettersson 2019).

In Malaysia, we still have time to start preparing ourselves in case the situation worsens and the ministry has to enforce mitigation measures (Dohlan and Ishak 2017). By all means, stock up on non-perishable items to last for about two weeks, however, we need to avoid excessive hoarding of goods, which can cause a shortage of these goods and create panic in the community. Those on regular prescription drugs for chronic diseases like diabetes, heart conditions, liver disease, kidney disease, cancer, and chronic respiratory illnesses should get additional supplies of their medication sufficient for an extra month (Bernama 2020) and stock up on face masks and hand sanitizers are top in the list as well. This is very disruptive of social life and requires the cooperation and commitment of the public (Bernama 2020; Davis 2019; Doyle 2020).

COVID-19 IN SCHOOL: NEW NORM

COVID-19 pandemic is revealing new layers of inequity that may end up setting us back even further. Education leaders are tackling the unexpected challenge of providing distance learning as the primary mode of instruction for weeks, months, and possibly the remainder of the school year (Bernama 2020; Azmy et al., 2016; Ana 2020). Rescheduling the school academic calendar and public exams as an immediate measure is reasonable but this action plan must be reviewed for the coming school session. Public exams will have to be examined thoroughly, and appropriate alternate assessment has to be the new norm in schools and institutions of higher learning (Bernama 2020; Azmy et al., 2016; Dohlan and Ishak 2017; Mulyanti et al., 2020).

The conventional written test has to go and assessments must be revamped. The Minister of Education (MOE) has announced that if schools are to reopen in the near future, each class should only accommodate 16 to 17 students at any one time (Bernama 2020). This is to ensure social distancing to prevent the possible spread of the COVID-19 virus. While it is good to hear that the ministry is making plans to bring students back to school, it must ensure that the schools, the teachers and other staff are fully prepared to operate under the new norm (Rodriguez and Rodriguez 2015; Cosner 2014). The new conditions and new norms should include the following:

1. Utmost consideration must be given to ensure that the ministry is able to ensure the safety and health of all students before sending them back to school;
2. As social distancing is going to be the practice, teachers must be better prepared to teach in a new norm environment. New ways and methods of teaching are required.

Teachers must be consulted on this and a new schooling pedagogy based on the sop may need to be rolled out;

3. In addition to social distancing in classrooms, the schools must ensure students who return to school have their body temperature retaken and be provided with hand sanitizers and face masks, shoes must be sanitized before students enter classrooms; and
4. Teachers should be able to explain to students the necessity for social distancing while emphasizing that it is not the same thing as being anti-social. They must explain why this is necessary and that it is only meant to be a temporary measure.

COVID-19 IN LEARNING: INNOVATIVE NORM

The primary challenge is to ensure adequate access and readiness of the stakeholders, students and teachers to the digital world that “real” teaming maybe missed out for the lack of learners’ “readiness” for independent self-learning as well as teachers’ wellbeing and readiness for online teaching (Mansaray 2019; Khan et al., 2014; Naseri 2019). Hence, education 4.0 strategy is perfectly befitting in the new normal, even in potential emerging pandemics in near or far future (Kilber et al., 2014; Kemp 2019). However, there are challenges (Kapur 2018). Education 4.0 strategy includes but is not limited to:

1. Encouraging more remote learning where theoretical knowledge will be disseminated through virtual communications while practical skills will be taught face to face;
2. Project based learning targeted to ensure wide set of skill roles; and
3. Personalized teaching based on students’ independence and unique approach to studying and the ability to learn.

COVID-19 pandemic has changed education dramatically as it has increased the use of personal telecommunications gadgets such as smartphones which prior to this were prohibited from school grounds, for learning and teaching purposes (Khan et al., 2014; Naseri 2019). Teachers should develop their skills in terms of online teaching and home-based learning which would be the new normal in the teaching field as e-learning is the future of education (Abu 2016; Hall and Hord 2014; Hallinger 2018). Teachers need to improve their knowledge, competency, change of attitude and be ready to embrace the new normal in education especially those which are related to online learning. This preparation will be reflected in teaching, assessment, and dissemination of knowledge (Kilber et al., 2014).

Throughout the Movement Control Order (MCO) and the Conditional Movement Control Order (CMCO), teachers continue to impart knowledge via online platforms. Teachers need to have a paradigm shift to be able to accept the new scenario in global education in order to build a generation with digital literacy which is very important to face the challenges brought forth by the Fourth Industrial Revolution (IR 4.0) (Drucker 2017; Helmi et al., 2017). This global crisis has made an impact on the conventional teaching and learning as well as on the responsibilities of educators, rendering it more challenging and they have to adapt to the new normal condition that requires the process to be conducted online (Khan et al., 2014; Naseri 2019). Online tools such as Google Meet and Zoom allowed us to keep meetings running, we

came to terms with the concept of working from home, as opposed to the cubicle layout we have grown accustomed to. Schools and higher learning education are resorting to online and virtual classes, and teachers are finding ways to teach from home while taking care of their own children (Ng et al., 2008).

ROLE OF SCHOOL ADMINISTRATION IN COVID-19: NEW NORM VS. NEW NORMAL

Over the past few months, we have experienced an unprecedented shift in our way of life due to COVID-19. One phenomenon that is certain, we know that adjusting to change can be challenging: be it planned or unplanned, gradual or sudden, change is inevitable and very much part of being human (Al-alawi et al., 2019; Drucker 2017). School administrators can play an outsized role in providing the ultimate pressure test of an organization position and purpose, as what is decided today will define the future (Haris et al., 2017). Looking into the future, some of the most important skills that employers will be looking for will be creativity, Communications, and collaboration, alongside empathy and emotional Intelligence, and being able to work across demographic lines of differences to harness the power of the collective through effective teamwork (Naseri 2019).

Throw in a pandemic, along with changes to routines and plans for the weeks and months ahead in 2020, and it is more important than ever to acknowledge the challenges and difficulties that we face in light of COVID-19. Developing an awareness and sensitivity in the school leader to these perspectives requires an attention to the process by which schools change themselves and to the interpersonal facets of school organizational life (Mansaray 2019). Professional preparation would need to focus on introducing aspiring school leaders to the different epistemologies underlying their administrative practice, to help them understand how different constructions of reality can facilitate or thwart successful change (Drucker 2007; Helmi et al., 2017; Yulk 2013). Rather than considering the relative strengths and constraints of each lens, with an eye to deciding one set of lenses is inherently superior to another (Rodriguez and Rodriguez 2015; Cosner 2014).

The COVID-19 pandemic has resulted in educational institutions across the world being compelled to suddenly harness and utilize the suite of available technological tools to create content for remote learning for students in all sectors. This pandemic and its aftermath test the stamina of organizations to preserve, to endure, and to be resilient. In this new millennium that prioritizes life-long learning, the way forward is by utilizing technology and online education (Haris et al., 2017). The current context of education demands educators to have advanced literacy on the information technology (Azmy et al., 2016). Therefore, today's leaders need a careful preparation that extends beyond the boundaries of education and civilization. In addition, leaders need to be flexible with their current and future needs in line with current world demands (Mansaray 2019). Collaboration and support from various stakeholders are essential as the leader's rise lies in the support of his environment (Naseri 2019, 35-40, Maryanti et al., 2020). Furthermore, aspects related to risk management need to be implemented effectively in order for leaders to be prepared and actionable at all levels of MOE.

CONCLUSION

In conclusion, the ideas discussed here suggest that as we seek to restructure and change schools and redefine the role of the school administrators in those efforts, there is much we can learn during COVID-19. COVID-19 pandemic has merely hastened the arrival of what experts in the human resource and management fields have predicted is going to happen in the future anyway. Undeniably, there is an overall reevaluation of the significance and nature of everyone's work especially to the role of school administrators.

Chapter 434

NEW NORMS IN THE WORLD OF EDUCATION: THINK OUT OF THE BOX FROM MALAYSIAN SCHOOL ADMINISTRATOR'S PERSPECTIVE DURING PANDEMIC

Nazeri Mohammad^{1,*} and Arshad Jais²

¹Department of International Education Cooperation and Relation,
National Institute of Educational Management and Leadership,
Genting Highlands, Malaysia

²Kuching Science School, Sarawak, Malaysia

ABSTRACT

Online education is a hot topic that is widely concerned in various countries today. However, the education of our children and youth has to continue because staying idle is contrary to the constitutional foundation of civil societies. Online pedagogy is starting to flourish. In becoming a new normal, online, or digital teaching is a viable alternative to conventional face-to-face teaching and learning. In the era of mobile internet, countries around the world have made various effective attempts at online education, but online education is more of a supplement to school education, and large-scale normal online education lacks cases. The method of learning however largely depends on students' motivation; the motivation must come from students themselves. Beyond participating in the creation of norms, students must be given regular opportunities to interact with the norms through self-reflection, peer and class assessment, and discussion. The sudden and unpredictable nature of the COVID-19 crisis and its effect on work and enterprises call for a rethink of our way of life. Successful people in the coming decades need to be able to understand this interrelatedness and navigate across boundaries to leverage their differences and work in a globally collaborative way. Undeniably, there is an overall reevaluation of the significance and nature of everyone's work. The truth is, teaching online is not easy, but it can be done and can be rewarding. Increasing numbers of people are using their time during the Movement Control Order to build new skillsets, with an upsurge in enrolments in online learning. Therefore, the steps taken by our government

must be supported to break the chain of transmission quickly while maintaining the competence of our students.

Keywords: Malaysian School Administrator's Perspective, new norms, pandemic, the world of education

INTRODUCTION

Coronavirus disease (COVID-19) has brought the world to a standstill but it has also helped pinpoint weaknesses in the education sector and presented opportunities for new norms and changes to kick in. None can predict the true impact of the pandemic on the global economy, but at this pivotal moment, there are clear choices to be made (Bringle et al. 2016b; Heimans and Timms 2014). To accomplish this condition, school administrators should support executive leadership and share the burden while maintaining appropriate separation from management. The way in which school administrators do their work at this time will be a critical factor in an organization's ability to emerge from the current crisis and push forward into a new era of economic recovery and opportunity for the benefit of all stakeholders (Al-Alawi et al. 2019; Cavazotte et al. 2013; Hallinger 2018).

Digital learning will continue to be a crucial part of post-Movement Control Order (MCO) education. Besides making improvements on internet accessibility and ICT facilities, the current exam-centric, the fast-paced education system needs to change (Pursel et al. 2016; Schankin et al. 2016; Zhou et al. 2020). E-learning tools provide educators and students with access to resources they could not have had otherwise, no matter their status or location (Helm et al. 2015). This has become painfully evident during the MCO. The current system's definition of success is narrow and based mainly on grades rather than outcome attainment as well as competency and character building. Economically, every additional MCO day will have a damaging impact. Making a bad situation worse, global oil prices slumped to new lows because of the COVID-19 pandemic. This makes it even more difficult for Malaysia to jump-start its economy while being mindful of fiscal prudence. Therefore, it is now more crucial than ever to think out-of-the-box to bolster the government's resources to fund its post-COVID-19 economic recovery (Husnu et al. 2016; Azmy et al. 2016).

THINK OUT OF THE BOX

COVID-19 is a pandemic that illustrates how globally interconnected we are there is no longer such a thing as isolated issues and actions. The post-COVID-19 realm requires different ways of thinking and organizing the world. Educators across the world are experiencing new possibilities to do things differently and with greater flexibility resulting in potential benefits in accessibility to education for students across the world (Bringle 2016a; Rodriguez and Rodriguez 2015).

In Malaysia, the system is there, but there are things that can be done to make it better (Dolhan and Ishak 2017). Thinking outside the box may best be summarised by the assertion 'When you think outside the box, the box goes away'. Rethink the scheduling of classes in

line with remote learning. Thinking outside the box is not easy since it involves leaving the psychological comfort zone, becoming open to new ways of seeing the world, and being willing to explore (Naseri 2019). In this ever-changing global environment, young people require resilience and adaptability skills that are proving to be essential to navigating effectively through this pandemic. So, if that is the worst outcome, what should institutions do to prevent that? Understanding how to learn involves deeper skills than mastery of study skills. Emotional intelligence, emotional health, and an understanding of the learning process are clearly related. We might conclude, therefore, that a good learner is able to think outside the box, and that since teachers are, by definition, also learners, those good teachers are out-of-the-box thinkers (Davis 2019; Stapa and Mohammad 2019).

Outside of marshaling all their resources to provide students without internet connectivity the support they need to teach and learn online, there are a few principles to follow. First, wherever possible, create active learning experiences ones in which there is synchronous communication, required class sessions, frequent opportunities for students to answer questions and defend answers, debate their peers, tackle problems, and the like (Zhou et al. 2020). Zoom might be suitable technologies for that, but schools should also investigate using an active learning platform. Second, remember that online learning is not about putting the class front and center like the MOOCs did. That means that teaching certain concepts might not be best accomplished through lecture capture technologies, but instead by showing a multimedia clip, something from Khan Academy, a brief simulation, by letting students teach each other (Khan et al. 2014).

NEW NORMS IN THE WORLD OF EDUCATION

Norms are the agreements we make with each other. They represent community goals, and as such, all classroom members should be given the opportunity to contribute to their creation. Norms exist to be used by students, thus students must be able to define and explain them (Penton and Pettersson 2019; Philips et al. 2017). Additionally, choosing a few norms promote student familiarity and ownership of the norms. The community must be empowered and parents and teachers must rally together to build a strong support system amid this crisis (Schankin et al. 2016). The parents play a role in educating children when they are at home (Maryanti et al. 2020). This includes providing a conducive environment for learning and keeping distractions at bay. Parents must get their priorities right and they must be committed. The teachers and schools need strategies to ensure that learning outcomes are achieved (Pursel et al. 2016). Children need support when using online platforms. Parents and guardians need pedagogical competencies in assisting their children with online lessons as well. However, we are optimistic that things will fall into place eventually (Naseri 2019). Schools must maintain clear and constant communication with parents. A guide for parents who have to multitask between remote work, household responsibilities, and helping their children with school work, is needed. Parents and guardians can also build their own support system via chat and social media groups to exchange ideas and experiences (Hashim et al. 2020). We need a video library with content developed according to the national syllabus and curriculum, and accessible via digital devices. Rethink the scheduling of classes in line with remote learning. Physical attendance is only for teachers and students to touch base (Schankin

et al. 2016). This method of learning however largely depends on students' motivation; the motivation must come from students themselves. Unfortunately, it will inadvertently filter those who want to learn and those who are less interested. Classrooms are made smaller to make it easier for teachers to get to know and engage with the students and parents (Bringle et al. 2016b).

These risk-control decisions have led millions of students into temporary homeschooling situations, especially in some of the most heavily impacted countries, like China, South Korea, Italy, and Iran. These changes have certainly caused a degree of inconvenience, but they have also prompted new examples of educational innovation. Although it is too early to judge how reactions to COVID-19 affect education systems around the world, there are signs suggesting that it could have a lasting impact on the trajectory of learning innovation and digitization. While school closures seem to present a logical solution to enforcing social distancing within communities, prolonged closures tend to have a disproportionately negative impact on the most vulnerable students. What we are learning from COVID-19, similar to what we have seen in previous pandemics, is that preparedness is crucial (Sangsawang 2020). While different scenarios exist, several of them assume that the COVID-19 spread will happen in waves, which means the process of addressing it should be cyclical.

EDUCATION NUDGED AND PUSHED TO CHANGE COULD LEAD TO SURPRISING INNOVATIONS

The COVID-19 pandemic has brought about a dramatic interruption in the way we do schooling across the globe. The slow pace of change in academic institutions globally is lamentable, with centuries-old, lecture-based approaches to teaching, entrenched institutional biases, and outmoded classrooms. However, COVID-19 has become a catalyst for educational institutions worldwide to search for innovative solutions in a relatively short period of time. In just the past few weeks, we have seen learning consortiums and coalitions taking shape, with diverse stakeholders including governments, publishers, education professionals, technology providers, and telecom network operators coming together to utilize digital platforms as a temporary solution to the crisis. In emerging countries where education has predominantly been provided by the government, this could become a prevalent and consequential trend to future education (Rodriguez and Rodriguez 2015).

THE DIGITAL DIVIDE COULD WIDEN

Most schools in affected areas are finding stop-gap solutions to continue teaching, but the quality of learning is heavily dependent on the level and quality of digital access. After all, only around 60% of the globe's population is online. Moreover, the less affluent and digitally savvy individual families are, the further their students are left behind. When classes transition online, these children lose out because of the cost of digital devices and data plans. Unless access costs decrease and quality of access increase in all countries, the gap in education quality, and thus socioeconomic equality will be further exacerbated (Bringle et al. 2016b).

The digital divide could become more extreme if educational access is dictated by access to the latest technologies (Firmansyah and Rahmawati 2018). Nobody thinks this is the way online education should be done. When students have expectations of face-to-face training, if the substitute for an emergency is proposed as interaction through a forum or a platform with limitations, satisfaction levels drop, because there is an apparent gap in those expectations, and students may prefer to postpone their course and wait for normal service to resume (Helms et al. 2015). If the substitution is carried out with a tool rich in interaction, this happens less often. Although e-learning from home is unavoidable in the current situation, the students are not able to focus as much as they can in a classroom. One of the ways e-learning has tried to mimic the social aspects of a classroom is with tools like message boards, Facebook groups, and yes, sometimes chatbots (Harisriani and Danuwijaya 2019). They give students the sense they are not just staring at an empty message board, but they are talking with real people about their homework (Kahn et al. 2014).

However, the pandemic is also an opportunity to remind ourselves of the skills students need in this unpredictable world such as informed decision making, creative problem solving, and perhaps above all, adaptability. The rapid spread of COVID-19 has demonstrated the importance of building resilience to face various threats, from pandemic disease to extremist violence to climate insecurity, and even, yes, rapid technological change. In our view as long as there is strict adherence to the safety guidelines and standard operating procedure (SOP), limiting the number of students to a class should not be an issue. Teaching and learning through online platforms must be strengthened as e-learning is the future of education (Ana 2020). The clear opportunity that has come out of this period is to press the "reset" button and we see areas where one can rebuild by recalibrating the mindset. The first thing that we need to do is upskill and reskill ourselves more intensively.

CONCLUSION

The COVID-19 pandemic will likely continue presenting challenges beyond those that come up in the course of routine virtual education. Even if this viral spread subsides, or a vaccination becomes readily available, the shift from online classes back to in-person learning may create disruptions of its own adjusting back to higher standards of accountability, weaning off of phone-checking habits, and transferring comments back to hard copies instead of digital notes. Hopefully, these experiences will serve as preparation for future challenges that come with the next epidemic, pandemic, and other disasters.

²Faculty of Postgraduate, Universitas Komputer Indonesia,
Bandung, Jawa Barat, Indonesia

ABSTRACT

The economic decline becomes the most severe phenomenon that hit the world besides the medical impact of the coronavirus outbreak. Southeast Asia countries as the middle-income countries require a better strategy to successfully respond to Coronavirus Disease 2019 (COVID-19) pandemic. Moreover, the highly uncertain condition makes it difficult for the affected companies' management in decision and policy-making. Therefore, this chapter aimed to develop better risk and a crisis management as the right response towards rapid and sudden change in crisis situation. In particular, it suggests ways that decision makers can adjust their company management for dealing with the extreme condition. The chapter explored risk and crisis management of some management experts using descriptive analysis, literature review, and qualitative technique. The chapter resulted in risk and crisis management strategies for reducing losses but at the same time providing protection for their employee considering people's safety is second to none. The way of how companies react will bring big impacts to control the economic downturn in the middle of a global recession that now seems inevitable.

Keywords: pandemics, risk and crisis management, companies, South East Asia

INTRODUCTION

The emergence of Coronavirus Disease 2019 (COVID-19) pandemic causes large-scale mortality and morbidity, trade and travel networks disruption, as well as stimulating civil unrest (Di Marco et al. 2020). This is not the first time when global pandemic led the world economy to devastation. The SARS outbreak in 2003, the H1N1 pandemic in 2009, and the West African Ebola outbreak from 2013 to 2016 each have caused economic damages by more than US\$ 10 billion. The current outbreak of COVID-19 once again hit the world with the huge socio-economic impact caused by international travel restriction and the quarantining of people in almost all affected countries. The considerable crisis hit almost all companies, especially in the field of tourism such as hotels, resorts, restaurants, and airlines. The disruption of supply chains also incredibly affected food, medicines, and the manufactured products industry. The economic impact is estimated to be higher than the US \$150 billion (Smith et al. 2019). On the focus as company management and from the point of view of a manager, COVID-19 that is spreading human suffering in economics has brought uncertainty conditions in all affected companies (Machmud and Minghat 2020). This extraordinary condition pushed them to provide risk analysis and risk management in order to minimize the financial and psychological loss.

Southeast Asia which is occupied by most of the middle-income countries and developing countries must prepare the appropriate strategy since the crises is predicted to be worse than the developed countries. Loayza and Pennings (2020) in their research stated that the developing countries can be more severely affected by economic crises besides mass unemployment and business closures. Its ripple effects can produce a set of other crises which are financial, sectoral, balance-of-payments, and debt crises. Furthermore, this extreme pandemic may cause a humanitarian crisis such as worsening poverty, a dire decline of basic social services in education, health, safety, and stimulating social conflict, violence, and crime (Loayza and Pennings 2020). There are 11 affected countries in South East Asia namely: Singapore, Indonesia, Philippines, Malaysia, Thailand, Vietnam, Brunei Darussalam, Cambodia, Myanmar, Laos, and Timor Leste (Sirkeci and Yucesahin 2020). The updated data on 20 April, 2020 showed that the high number of cases is suffered by Singapore, while the highest mortality number in South Asia is suffered by Indonesia (World Health Organization 2020). Even though the crisis caused by the pandemic is global, the response to anticipate the impact is local. However, different countries show different approaches in responses as well as different companies react differently toward the resulting crisis.

Extreme efforts are needed in an extreme situation. Companies need to know the risks that might occur and what risk mitigation strategies can be applied to overcome the risks. Managerial implications need to be taken from the risk analysis to make a better effect on the company (Giannakis and Papadopoulos 2016). There are several studies concerning risk analysis where the researchers predict and measure the loss caused by the COVID-19 pandemic. A research confirmed that today, Composite Stock Price Index (IHSG) significantly decreased and lost almost 50% from the initial value on December 2019 (Utari, 2015). Asian Development Bank in its research estimated a global impact of US\$77 to US\$347 billion (or 0.1% to 0.4% of global GDP) (Dayrit and Mendoza, 2020). In line with this, the Center for Economic Policy and Research stated that COVID-19 hit many factories in Asia, especially in China, Japan, the Republic of Korea, and Singapore. Collectively, the

United States, China, Japan, Germany, UK, France, and Italy account for 60% of the global economy, 65% of global manufacturing, and 41% of global manufactured exports (Maliszewska et al. 2020). The World Health Organization (WHO) researchers predicted that East Asia and Pacific (EAP) will suffer the biggest GDP losses countries due to their relatively deep integration through trade and direct impact on tourism, as an example Cambodia (3.20 %), Singapore (2.10 %), China (2.30 %), Thailand (3 %), Vietnam (2.70 %), and Malaysia (2.10 %) (Mendoza, 2020). However, the paper describing risk management from the point of view of practitioners; in this terms company management; is required to broaden insight in building better risk management. It is crucial for all companies' management to have sufficient knowledge concerning risk and crisis management including taking preventive action, predicting upcoming uncertainty, building adjustment, and developing adaptation ability to survive in the long run.

This chapter attempts to develop better risk management as the right response toward rapid and sudden change. In particular, it suggests ways that the decision-makers can adjust company management for dealing with extreme condition. The chapter used descriptive analysis, literature study, and qualitative method in order to present a well-described subject.

WHAT IS THE RISK? HOW IT CAN BE DIFFERENT FROM THE CRISIS?

In summary, the risk is anything that negatively impacts the achievement of objectives as measured by their likelihood and impact. Risk can be defined as the actual deviation from the expected yield (Gollier 2018). The definition of risk is emphasized on the negative impact of achieving goals, although the exact definition is still growing. The definition of risk is still debatable considering the fact that well-measured and well-managed risk can increase innovation and greater opportunity to achieve goals (positive impact). On the other hand, the terms of crisis refer to dangerous situations that have a huge impact on everyone which can be caused by several factors such as the plague, natural disaster, technology, bad management, terrorism, war, and scarcity (Tong and Zhang 2020), whereas crisis management can be interpreted as a process that addresses organizations with a major event that threatens to harm the organization, stakeholders, or the general public. There are three elements that are most common for defining crises: threats to the organization, elements of surprise, and short time decisions. Unlike risk management, which involves assessing potential threats and finding the best way to avoid threats, crisis management deals more with threats that have already occurred.

The crisis which is assessed through the business perspective is a situation that leads to greater intensity of the problem, disruption of daily business running, affecting the image of the company, interfering company's overall work system, affecting community social pattern. In facing the crisis, the government has the authority to intervene. In facing the risk, the company has its authority to solve the problem. The common thing from risk and crisis that is both cases may trigger companies in conducting transformation and building resilience through the hard conditions. In a good response, both conditions may become a catalyst for companies to get better and survive in the long run (Martin et al. 2017).

TYPES OF RISK VERSUS TYPES OF CRISIS

Risks can be classified differently depending on which segment of business operations they are related to. Risks are divided into two categories: internal and external risks (Salamai et al. 2019). Business risks that occur within the business activities in the companies are called internal business risks and including the following external business risks which are sources that are outside the company such as the COVID-19 pandemic. The size of risk can be predicted from the data released by WHO regarding the decline in GDP and export illustrated in Figure 1.

Figure 1 shows the decreasing of GDP that is predicted to be experienced by several countries in East Asia Pacific (EAP) released by the World Health Organization (WHO). Global GDP is expected to decrease by 2.10%, while developing and high-income countries' GDP is expected to decrease by 2.50 and 1.90%, respectively. Moreover, exports at a global level are expected to decrease by 2.50%. China is predicted to suffer a decrease in production across all sectors and goods as well as showing a reduction in exports of 3.70%. Vietnam shows a decrease in its total exports by only 1% because Vietnam fills the gap left by the decrease in Chinese exports. China is the most affected country in the East Asia and Pacific region in terms of export declines, followed by Laos (3.60%), Cambodia (3.90%), and Singapore (4.40%) (Barua 2020a).

Figure 1. GDP and export implication of global pandemic scenario for EAP countries (% deviation) from the benchmark (World Health Organization 2020).

People quarantined in almost every affected area have disrupted the supply chain due to the underutilization of labor and capital. Moreover, with an increase in its trade costs, the import costs for the rest of the world turns into a decline in global exports. The decline will lead to an economic crisis. Company management needs to have good knowledge concerning the stages of the crisis, which are divided into several stages, namely prodromal or symptoms of the crisis, acute, chronic, and healing (Bundy et al. 2017).

At the stage of Prodromal or Symptoms of Crisis, all events or signals of the crisis have begun to appear but the company continues to carry out activities as usual. If the company cannot catch this signal by not implementing crisis management, it will have a big impact on the next stage. As an example, when a company hears that coronavirus had spread in various countries but Indonesia has not yet had an impact, then this is a signal for the company to prepare a strategy if the virus enters Indonesia so that at the next stage, the company can survive.

At the acute stage, the crisis is not so obvious but has begun to be felt slowly by the company. At this stage, the term “point of no return” also means the company has no chance to re-improve the situation if the signal in the prodromal process is not heeded by doing good crisis management. For example, when the government firstly found the COVID-19 cases in Indonesia, the company continued to run the company as usual and prepared scenarios for alternative work such as working from home.

At this chronic stage, government intervention has emerged and affected the entire business process as a whole because the company has had an impact on the crisis. It is at this stage that the company implements a strategic policy so that the business can continue working. As an example, when Jakarta or Indonesia is on the lockdown, it can affect overall business activities such as supply chains and also export or import activities.

The last stage of the crisis is the healing stage. The company will begin to improve and reorganize the workings and structure of human resources. However, at this time, the company also began to adapt to all conditions if the company experienced a crisis that was quite long (Barro 1991).

THREE ASSUMPTIONS ON RISK AND CRISIS MANAGEMENT PLANNING

Quick Recovery Assumption

In a quick recovery assumption, we assume that the COVID-19 pandemic will be overcome before the end of this year. Community transmissions in East Asia and Europe are brought under control. Consumer confidence also starts to return, even in the setting of sustained transmission, due to lower case fatality ratio, case-growth slowdown, and promising treatment options. Aviation, tourism, and hospitality sectors back to normal as countries lift travel bans (Maliazewaka et al. 2020). In this assumption, companies must design strategies by identifying crisis threats and opportunities. Companies must also be able to analyze the company's SWOT in facing a crisis as well as made a long-term strategy preparation. In this situation, a manager should translate theoretical planning into reality and practicing the responses with appropriate personnel and other resources. For this condition, management should involve senior members who have sufficient experience and knowledge to design risk and crisis management planning. After those who familiar with the situation conducting an analysis, companies need to implement strategic programs in dealing with crises.

Slow Down Recovery Assumption

A slowdown recovery assumption has been indicated with the transmission case in East Asia and the Middle East, while transmission in Europe is still growing (Maliazewaka et al. 2020). Consumer confidence also remains decrease. Demand recovery depends on the evolution of disease; some sectors (e.g., consumer goods) recover faster. It is too early to predict when the COVID-19 will be resolved. This also causes the vagueness of many companies about their priorities at the end of this pandemic. This is not surprising as it is difficult to predict what position the company will be in or what resources will be available in this assumption. The impact on business continuity is likely to be severe in a slow-down recovery assumption. However, in this condition, communication management and trust are very important in building resilience to a “shocking” impact. Communication management between governments, non-governmental organizations, media, and telecommunications in times of crisis should be well-maintained to make problem mapping easier.

Pessimistic (Recession) Assumption

The pessimistic assumption is indicated with the expansion of disease to other parts of the world, including confirmed transmissions in the rest of North America, Africa, and India. Consumer confidence remains low, and air-travel restrictions remain in place until late 2020 (Maliazewaka et al. 2020). During the time when we were writing this chapter, the pandemic has not reached its peak yet. The researchers predict the second phase of COVID-19. The worse assumption should be made to make companies well-prepared with this ongoing crisis.

The following are the suggested steps as risk and crisis management in all assumptions, especially in the worst condition.

Maintaining Good Communication

The COVID-19 crisis has stimulating civil unrest and labor demonstration. Communication by those who oversee the situation is often critical. Maintaining good communication also means protecting employees. This pandemic has been disturbing either mentally or economically. Therefore, good communication can stimulate resilience toward the worst assumption of the COVID-19 crisis. Since the pandemic tremendously changes the way of work and the way of life, then giving support to employees becomes more crucial. Report and socialization of new policy must be conveyed by those who have good communication skills. Leaders and top management should communicate their policy continuously to the employees.

Create a Special Team

Companies should create a special team to handle the crisis. The team is assigned to monitor the physical health and psychological condition of the employees. Companies should

provide online consultation and counseling services to reduce the stress of the employees. The team should update information related to the socio-economic conditions, report to the CEO, and inform the employees. Supply chain monitoring should also become their work priority as well as the sales number. The information must be transferred to a related division for forecasting risk and designing a good response. This team should design specific daily, weekly, and monthly targets by continuing adjustment to recent conditions. They must define priority in the effort to overcome the crisis, determine the most valuable people in the company, and make sure the liquidity of the company.

Supply Chain Management

Company management is suggested to find the second supplier. This step aims to find suppliers of raw materials with a closer location. This step has a positive side of greater long-term supply chain resilience. Safety stock and recalculate raw material inventory is also an effort that can help to maintain the supply chain. This step aims to consider the resilience of ready raw material stock for production to deal with the fluctuations in demand in times of crisis.

Customer Management

This pandemic has caused a downturn in direct sales (face-to-face method). The company management must adjust their method to maintain customer loyalty. Online sales obviously have become a new trend in the pandemic era (Dirgantari et al. 2020) Stay at home as social distancing jargon means that people are purchasing products from home. This must stimulate every company to make digital transformation and strengthen digital infrastructure.

Change the Risk into Opportunity

Several companies have changed their production to product mask, medical equipment, and many more to find opportunity in the middle of the crisis. Of course, this cannot be conducted by all companies. Creating some innovations in sales and promotions also become crucial needs for companies to survive against the crisis.

Growth is Replaced with Survival Strategies

Several business sectors are predicted to experience the worst impact of a pandemic. In these sectors, survival strategies should be well-planned to replace growth strategies. The rapid response should be managed to allocate company resources in the effort to overcome the crisis overall rather than just increasing sales targets. Below is some analysis of business continuity in the most affected sectors:

Tourism

Travel restrictions have been widely applied to minimize the spreading of COVID-19. Travel restriction is defined as government order to stay at home and prohibition to move to other jurisdictions and closure of international borders. The exception of travel restriction is made for permanent residents and essential services. Meanwhile, the closure of international border is not enforced for returning nationals and permanent residents/visa holders (Wilson et al. 2020). The tourism industry contributes around 10.3% of global gross domestic product and generates roughly one in four of the world's new jobs over the past five years. Travel restriction in such an extreme manner in almost all territories around the world would result in more than 100 million job losses this year. Asia is suffering the biggest job losses in this sector; with a total of 60 million job losses; compare to other continents (UNWTO 2020). Short- and long-term survival strategies show the organization's capacity to respond to a crisis.

The tourism product is included in the service which is intangible. It is also complex since it consists of numerous different service providers and organizations. Hotel service, transportation companies, restaurants, tourism destination management/private sector, media, local community, and government/public sector are engaged in the tourism image. These service providers should contribute to the creation of favorable images for the fast recovery of the tourism sector. However, the safety aspect is the most important for the customer to visit tourism after the pandemic. In addition, the investment in human resource management in responding and managing crises has become a major risk mitigation issue for organizations in the tourism sector. Thus, resources investment in HRM initiatives involving to change corporate culture to deal effectively with crisis situations benefit organizations in both ethical and business perspectives (Mitroff 2004; Pforr and Hosie 2008). The holistic approach should be created by involving all stakeholders. The media has a role to deliver correct and consistent information and support image rejuvenation. The government should take an action in determination of tax incentives, special import provision to stimulate foreign investment, tax relief, extended credit to businesses, increased funding. The private sector should focus on marketing and promotions and the best way to handling customers. The local community has the role to inform tourists about the situation and security advice at the destination (Martents et al. 2016).

Properties

The decrease in economic growth and purchasing power due to pandemic has a tremendous impact on the decline of demands in the properties sector. The other impact of the crisis was the fund withdrawing by the investors, and temporarily discontinuation of distributing credit from the bank to the property sector. As the survival strategy, the property companies should shift their marketing target to Suburban areas since the demand in this area may increase due to businesses relocating from areas that have been quarantined. The strategy will keep the fixed costs for businesses holding leases at the same number, even in the face of declining occupancy and declining revenue (Sikich and Gear 2018).

Utilities (Electric, Gas and Other Infrastructure Power Supplies)

The great track record as a provider of critical infrastructure in the pandemic makes the utility company to be responsive to emergency situation. The global pandemic could stimulate the permanent destabilization of the power and utility sector. The high loss of workforce has led to respond ability decreasing in the maintenance. Furthermore, the inability to meet demands resulting in the prices increasing for energy and related products. The high demand for information systems to operate facilities and pipelines creates security vulnerabilities for this industry (Sikich and Geary 2018). The information system should develop to create clean and efficient energy. Although, during the pandemic, the domestic electricity consumption increased because most people were staying at home. On the other hand, the pandemic has pursued the rapid growth of renewable energy. Hence, the focus of recovery strategy in this sector should be focused on the security of energy supply and creates innovation in renewable energy (Wang et al. 2020).

Communications Industry (Voice, Data and Other Information Systems)

Work from home becomes the most popular word during the pandemic. Through technology, people are enabled to work remotely and at the same time also enable greater information exchange. Economists predict that fixed costs remain unchanged regardless of demand in this sector (Sikich and Geary 2018). The high demand for this sector should be answered with a high investment in the skillful personnel. Human resource management should create a good system to prevent the loss of skilled workforce since it creates potential system vulnerabilities

Banking and Finance

The disruption of worldwide economy is experiencing by the banking and finance sector. However, severe outbreaks are not new for countries in Asia. The COVID-19 outbreak was often likened to the SARS epidemic in 2003, which hit mainland China, Hong Kong, and Singapore very hard, and plunged each country's economy into a recession that makes the local government better equipped to deal with a similar crisis. Major economies in Asia have learned from past crises and built strong financial balances to reduce their economies in the face of external shocks. Governments in the Asian region are also learning quickly from China's response to the outbreak. In addition, companies in Asia also have stronger cash positions. Asian and Western markets show that more Asian companies have a net cash position, which means they have the ability to reinvest in the business and potentially gain market share (Bloom et al. 2005).

Transportation

The transportation sector has become the worst devastated caused by the pandemic of COVID-19. The travel restriction, quarantine of thousand people worldwide, flight restrictions, lack of workforce, inability to ship goods to markets has made this sector experience the tremendous impact that hard to be recovered (Barua 2020). This pandemic makes people even more reluctant to switch to using public transportation because of the high concern over the transmission of COVID-19 in public spaces. We need greater efforts to get out of the crisis situation that arises in the transportation sector. The government policy to give the secure feeling to the people to use transportation is urgently needed. This effort must be supported by the discipline culture of citizens and the management of public transportation company.

CONCLUSION

This paper has presented three assumptions in risk and crisis management in the COVID-19 outbreak that might evolve. Pandemic risks may largely jeopardize the market position and financial position of affected companies in South East Asia. Even more, South East Asia which is occupied by developing countries will suffer more economic destruction compared to developed countries. Pandemic is global, but the response is local. The way of how companies react will bring big impacts to control the economic downturn in the middle of a global recession that now seems inevitable. The company management cannot merely think about the plannable or plan for the unthinkable, but they must learn to think about business continuity planning in the unplannable situation such as pandemic of COVID-19.

Universitas Pendidikan Indonesia, Bandung, Jawa Barat, Indonesia

ABSTRACT

This study aimed to analyze the impact of corona virus disease 2019 (COVID-19) pandemic on the Indonesian economy. The study used a descriptive qualitative method, with the main study data taken from several articles published in several mass media and journals. The results of the study showed that the COVID-19 pandemic had a significant impact on the Indonesian economy, which in turn predicted Indonesia's economic growth in two scenarios: 2.3% (heavy) and minus 0.4% (very heavy). The implication of this finding is that the Indonesian government should prepare various post-pandemic COVID-19 policies both related to fiscal and monetary fields.

Keywords: COVID-19, economy, economic growth, pandemic

INTRODUCTION

World Health Organization (WHO) announced on 11 March 2020 regarding the change in the status of corona virus disease 2019 (COVID-19) to a pandemic. This is because of a significant increase in the number of case reports and the number of deaths from COVID-19 in whole part in the world (De Groot-Mijnes et al., 2005; Word Health Organization 2020). This pandemic has made a substantial impact on all the economic sectors. It is already widely-known that before developing into a pandemic, this virus was initially discovered in Wuhan City, Hubei Province, China in December 2019.

* Corresponding Author's Email: amir@upi.edu.

COVID-19 is a type of corona virus. This virus comes from animals or we use the term zoonotic (Maryanti et al., 2020a). This virus is very dangerous because it can infect the human body and result in death. This virus enters the human body through the nose and mouth (Maryanti et al., 2020b). This virus infects organs in the human body such as the digestive organs, liver, and lungs. People with COVID-19 usually experience symptoms of shortness of breath and fever. This virus is transmitted through droplets either directly or indirectly. The very small size of the virus results in the virus being easily transmitted and infecting the human body.

The number of confirmed COVID-19 cases from 22 January to 31 March 2020 experienced a significant surge (Ana 2020; Anggraeni et al., 2020). The number of case reports worldwide was 802,639 with a total of 39,014 deaths and a total of 172,319 patients recovered (Huang et al., 2020; Zhu et al., 2020; Li et al., 2020; Machmud and Minghat 2020).

The COVID-19 pandemic caused problems in various aspects in life. The COVID-19 pandemic also has an impact on economic, social, educational and public welfare aspects. In the economic aspect, it is possible to have inflation due to price increases (Machmud and Minghat 2020). In the educational aspect, it creates new problems for teachers and parents in the learning process for children. There are several conditions for children that do not allow distance learning (Maryanti et al., 2020b; Mulyanti 2020). Economic factors, infrastructure, and student abilities are the main factors in educational problems.

This study analyzed the impact of COVID-19 on Indonesian economy. The study was motivated by a decline in the level of consumption and investment that led to the economy as a whole. The call for physical distancing, working from home (WFH), studying from home (SFH), worshipping at home, and the prohibition of activities has caused the economic wheel to be almost stagnant. This study used a qualitative descriptive method by describing the phenomena that occurred due to the impact of the COVID-19 on the Indonesian economy. The source of the study referred to several articles published in several mass media and journals.

THE IMPACT OF COVID-19 ON THE INDONESIAN ECONOMY

The impact of the COVID-19 pandemic on the economy is shown by the potential for shocks in the demand and supply of goods and services (Binder, 2020). From the supply side, the policy of physical distancing, social distancing, working from home, and staying at home caused a decline in the production activities in addition to the difficulties in the distribution of goods, while the demand side experienced a significant increase due to panic buying in meeting basic needs (Leung, Lam and Cheng 2020). This condition resulted in an increase in the prices of goods on the market (inflation). Indeed, it would ultimately reduce the purchasing power of the people, resulting in losses to producers which could result in high unemployment (Machmud and Minghat 2020; Weitzman 1982). Another economic impact is that the exchange rate of the Indonesian rupiah (IDR) against the US dollar (USD) has penetrated almost 1 USD = 17.000 IDR. This condition will have an impact on rising prices for imported goods, which incidentally still has a substantial number of goods needed by the people coming from imports. This condition is not surprising that there will lead to an economic crisis (Phelps 1968).

The Indonesian Central Statistics Agency (BPS) reported that the number of foreign tourist arrivals (tourists) recorded was 885,067 in February 2019. It decreased by 30.42% compared to the previous month and 28.85% compared to the same period in 2019. The decline in the number of foreign tourists is inseparable from the regional quarantine policy (lockdown) conducted by many countries in the world. A very significant decrease came from Chinese and Hong Kong tourists either year-on-year or month-to-month. The decline reached 94% from China and Hong Kong, down by 93.16% year on year, from February 2019 to February 2020 (Sugihamretha 2020).

Other impacts also affected the Indonesian capital market. While on the country's stock exchange, the Composite Stock Price Index (CSPI) on the trading day as of 7 April 2020 was corrected by 0.69% to 4,778.64 IDR. The transaction value on the Indonesia Stock Exchange (IDX) reached 9.6 trillion IDR with a record net sell of 527.65 billion IDR in the regular and non-regular markets. This condition shows that during the first quarter of 2020, CSPI recorded a decline of almost 28%. The most severe selling occurred in March 2020 which collapsed to value of 16.76%. Even on last 24 March 2020, the Jakarta Composite Index touched 3,911,716 IDR, the lowest level since August 2019 (Silalahi and Ginting 2020).

During the COVID-19 pandemic, the Indonesian government announced additional spending and financing for the 2020 state budget for handling COVID-19, amounting to 405.1 trillion IDR with allocations for social protection for 110 trillion IDR, health by 75 trillion IDR, tax incentives and stimulus for People's Business Credit (KUR) of 70.1 trillion IDR, as well as for financing the national economic recovery program of 150 trillion IDR, including credit restructuring and guarantees as well as SMEs and business financing to maintain economic resilience and recovery (Astuti and Mahardhika 2020).

As a further step to strengthen monetary and financial market stability together with Bank Indonesia, the Coordinating Ministry for Economic Affairs, the Ministry of Finance, the Financial Services Authority (OJK) and the Deposit Insurance Corporation (LPS) have made a policy mix in order to strengthen economic stimulus in accordance with the authority of BI in the Government Regulation in lieu of the Act Law (Perpu) No. 1 Year 2020 dated 31 March 2020 concerning State Financial Policy and Financial System Stability for Handling the COVID-19 pandemic and/or in the context of dealing with threats that endangered the national economy and/or financial system stability signed by President Jokowi, The policy mix is at least as follows:

1. Reducing BI 7-Day Reverse Repo Rate (BI7DDR) policy rates in February and March by 25 bps;
2. Increasing the intensity of triple intervention in the spot market, Domestic Non Delivery Forward (DNDF), and purchasing loan letter (SBN) in the secondary market;
3. Reducing the minimum mandatory giro (GWM) of conventional commercial bank foreign exchanges from 8 to 4%;
4. Extending the SBN repo tenor and auction every day to strengthen the easing of rupiah liquidity and increase the frequency of FX Swap auctions to every day to ensure adequate liquidity;
5. Extending the underlying DNDF transaction types so that they can hedge the ownership of ownership Rupiah in Indonesia;

6. Reducing Rupiah GWM by 50 bps for banks conducting export-import activities, financing to SMEs and/or other priority sectors;
7. Loosening the provisions of Macroprudential Intermediation Ratio (RIM); and
8. Providing hygienic money, reducing costs Payment System in Indonesia (SKNBI), the establishment of a 0% QR Code Indonesian Standard (QRIS) *Merchant Discount Rate* (MDR) for micro business merchants, and supports the distribution of non-cash funds for government programs such as the Hope Family Program (PKH) and Non-Cash Food Aid (BNPT) Social Assistance Program, the Workers Card Program, and the Smart Indonesia Card (Masudin et al., 2020).

Based on the above conditions, the overall COVID-19 pandemic has negatively influenced Indonesia's economic growth. Sri Mulyani Indrawati, Indonesia Minister of Finance, predicted two possible scenarios that occurred on Indonesia's economic growth as the impact of the COVID-19 pandemic, namely heavy and very heavy.

In a severe scenario, GDP is predicted to grow 2.3%, while this year's very scenario of economic growth could be minus 0.4%. This condition caused a significant decline in economic activities and has the potential to put pressure on financial institutions because credit cannot be paid while companies have experienced difficulties from revenues (Phan et al., 2020).

To deal with these conditions, the Indonesian government must have prepared various policies after the COVID-19 pandemic, which are both related to fiscal and monetary aspects. Quoting Ibn Khaldun's model of the father of Islamic economics, to maintain economic stability, it is possible to apply the Sharia Socio-Economic Dynamics Model (Affandi and Astuti 2013; Chapra 1999; Chapra 2008). The formulation of this model has eight important elements:

1. Government power (al-mulk) cannot be realized except by the implementation of Sharia;
2. Sharia cannot be implemented except by government (al-mulk);
3. The government cannot obtain power except from the people (ar-rijal);
4. Society cannot be supported except by wealth (al-mal);
5. Wealth cannot be obtained except from development (al-'imarah);
6. Development cannot be achieved except through justice (al-'adl);
7. Justice is a benchmark (al-mizan) that God will evaluate in His people; and
8. The government is charged with the responsibility to realize justice.

In the effort to recover Indonesia's economy, variables such as government, society, and law have important roles in bringing about the welfare of society. The economic recovery of a country will be realized depending on the strengths and weaknesses of the political authorities that they succeed in realizing.

CONCLUSION

The results of the study showed that the COVID-19 pandemic had a significant impact on the Indonesian economy, which in turn predicted Indonesia's economic growth in two

scenarios: 2.3% (heavy) and minus 0.4% (very heavy). This finding implies that the Indonesian government should prepare various post-pandemic COVID-19 policies both related to fiscal and monetary fields. This research is still in the stage of descriptive analysis related to the impact of the coronavirus on the global economy. Further other research can look at the impact of the coronavirus pandemic on society which is more focused on the conditions and behaviors that occur in society.

ABSTRACT

As the coronavirus disease 2019 (COVID-19) crisis continues around the world, consumer behavior on purchasing pattern has started to change. The outbreak of the COVID-19 has a major impact not only in the health sector but also on the economy, including on economic activities relating to the process of purchasing goods or services. The condition of the COVID-19 pandemic followed by the adoption of social distancing led to consumer new behavior in determining purchasing patterns or purchasing decisions. This paper investigated whether consumers purchase decisions are changing or not during the pandemic. This study used the literature study with secondary data support. It was found that consumers are shifting to online and digital shopping decisions through online media to reduced-contact channels. The results of the study are expected to be a reference for related parties, especially for suggesting some decision in the policy makers and government.

Keywords: buying decision, purchasing patterns, pandemic

INTRODUCTION

The world concern very well about the coronavirus 2019 (COVID-19) outbreak that occurred. The reality of this new pandemic surprised the world. Based on the Chinese National Health Commission until 12 a.m. on 4 February 2020, this pandemic has caused 20,471 people to be infected in China (including Hong Kong, Macao and 150 Taiwanese) and the Chinese National Health Commission has also confirmed that there are 23 countries outside China that have infected, including Indonesia (Wyplosz 2020; Dirgantari 2020). The positive number of COVID-19 in Indonesia has now reached five thousand cases as of 18 April 2020 with a death rate due to positive COVID-19 of 9.13%. As many as 8.68% of the number of people who are positive COVID-19 has recovered (This data was submitted by the Government Spokesperson for Handling COVID-19, Achmad Yurianto (Kompas 2020).

The increasing number of positive COVID-19 has affected many sectors such as tourism, aviation, health, mass media, government, e-commerce, social media, and entertainment media. The government has also made a policy to carry out all activities at home such as studying, working, and worshipping. So far, there have been 10 regions that have implemented Large-Scale Social Restrictions (known as PSBB) as an effort to break the spread of COVID-19. This is certainly increasingly limiting community activities outside the home, in which usually we can shop directly to markets or supermarket and nowadays people must shop Online. Indeed, this is easier and faster, and this does not have to gather with people (Kompas 2020).

During the COVID-19 pandemic, business competition was very fierce, reflected by the number of companies that sought to capture market share and new markets through a variety of ways and innovations displayed in the products or services they produced (Velavan et al., 2020). Companies must be able to determine the right marketing strategy so that the business can survive and the main objectives of the company can be achieved.

Several factors are the reason for a company to get its own place in the hearts of the community. For example, company must consider how a company sets competitive prices, conduct effective promotions, shape the image and build a good corporate reputation in the eyes of consumers, as well as good and satisfying quality of products. They also need to find ways to get their old customers back with a new mindset from the traditional mindset to the online mindset.

In most countries, customers adapt to make transactions, access Products, and services that are minimal in contact and digitally based (El Zowalaty et al., 2020). When consumers are restricted in shopping, they find and adopt newer ways to shop through technology. In countries badly affected by COVID-19, consumers begin to hoard food and other important items, and isolate themselves from the crowd. Thus, patterns in shopping change, and they adopt newer ways to shop through e-commerce (Buana 2020).

In this situation, people who were previously reluctant to shop online are now setting up online accounts on various e-commerce platforms, experiencing a completely new customer journey. Once they feel comfortable shopping online, they might never go back to their old ways. e-commerce has undermined offline retailing for a long time, but this pandemic has accelerated the trend (Bakhtiar 2020). The government also began to look at the e-commerce sector as one solution to overcome the tax deficit due to the economic slowdown. E-commerce has actually been able to attract many consumers in Indonesia before the COVID-

19 outbreak. E-commerce is also one of the main drivers of making Indonesia the country with the largest digital economic value in Southeast Asia reaching \$ 40 billion in 2019 and it is predicted to increase to \$ 130 billion by 2025. With more retail shops and consumers forced to turn to e-commerce, its growth can be increased and even further (Corbitt, Thanasankit and Yi 2013).

E-commerce or online shop, provides a variety of products needed by the community ranging from household needs, electronics, clothing, and others. They also provide various kinds of conveniences to consumers and various other promotions such as discounts, cashback, and other bonuses (Foster 2016). Various kinds of offers provided by this online shop certainly attract consumers to shop. With the closure of physical stores, brands are increasingly pivoting to a direct-to-consumer (D2C) business model. D2C brands have a simplified proposition that cuts out retailers – selling directly to consumers through mobile and digital channels. They can meet household needs easily and quickly. They still follow the rules applied without going out of the house, but the goods will arrive safely and securely with an online shop. The convenience provided in shopping is expected to help government programs to “stay at home” (Lucas et al., 2020; Dirgantari et al., 2020).

The use of various e-commerce services continues to increase, based on research conducted by similar web shows an increase of 2.05% in e-commerce in Indonesia within 28 days and will continue to increase as consumers spend more time to stay at home (SimiliarWeb 2020).

Thus, the purpose of this study was to find out how people’s buying patterns were during the COVID-19 pandemic outbreak. The results of this study are expected to provide information about businesses in selecting and determining strategies that can influence purchasing decisions with businesses able to survive in increasingly competitive competition during the COVID-19 pandemic outbreak.

METHOD

This research was a descriptive research with a literature study approach by finding references and theories, which were obtained as a research path for the study of literature serve as the basic foundation and the main tool for research practice in the middle of the field. The results of this study used to identify consumer buying patterns through changes in consumer behaviour in making purchasing decisions and strategies, so that companies could survive in increasingly fierce business competition during the COVID-19 pandemic outbreak.

RESULTS AND DISCUSSION

According to Kotler, a purchasing decision is a problem-solving process that consists of an analysis of needs and desires, information search, assessment of the source of selection for purchasing alternatives, purchasing decisions, and behaviour after purchase. In general, making a decision is the selection of actions from two or more alternative choices. Of the various factors that influence consumers in buying a product or service, consumers usually

always consider the quality, price, and products that have been previously identified (Said et al., 2020).

The purchase decision process includes five stages. These stages are

1. being aware of needs;
2. searching for information;
3. evaluating product alternatives;
4. making a purchase decision; and
5. post-purchase behaviour.

The buying process starts long before the actual purchase. Marketers need to focus on the entire buying process, instead of focusing on the purchase decision alone (Kotler and Armstrong 2018). The consumer decision-making process begins with them realizing their needs and insatiable desires. Then, the consumer will realize the difference between his actual status (as a case) and the ideal needs they want to meet through several social and psychological aspects. These needs are what motivate and stimulate them to make decisions (Mullins et al., 2011; Mullins et al., 2008). The importance of purchasing decisions appear, especially for shopping commodities. Risks that are a consequence of this decision are (Lahindah and Siahaan 2018):

1. functional risk: the product does not perform its function as expected;
2. financial risk: the product does not match (or is the same) as the price paid;
3. social risk: the product may endanger others;
4. psychological risk: products can affect (or influence) consumer from their consumers;
5. time risk: product failure can cause a loss of opportunity to be satisfied from consuming other alternative products.

To find out how and when consumers begin to show behavioural changes in making purchasing decisions, we conducted a study of shopper behaviour during the beginning of the pandemic in China and extended to other countries that were also affected. Current reports monitored a growing trend in the consumer environment when news of COVID-19 reached the public sphere and found that consumers went through six stages of knowledge based on their awareness of COVID-19 that spread in their communities (Velavan et al., 2020):

1. proactive health-minded buying: increasing interest in having a product that has a relationship in maintaining welfare or health.
2. Reactive health management: prioritizing products in an effort to prevent infection.
3. Panty preparation: increasing in product purchases that have a long-term shelf life and increase store visits.
4. Quarantined living preparation: increasing online shopping, decreased store visits and signs of supply chain irregularities.
5. Restricted living: increasing in prices due to limited availability and hinder the fulfilment of online needs.
6. Living a new normal: increasing health awareness when returning to their activities.

The literature on purchasing decisions explains that many factors influence purchasing decisions. Some factors that influence purchasing decisions include price, products and services (Basu et al., 1995). Consumers are willing to sacrifice their money to buy certain products if the product is able to meet their expectations (Parasuraman and Berry 1991). The evaluation of a product or service based on several considerations is only determined based on its external appearance, such as brand, price, or packaging, which directly or indirectly will affect the decision-making process (Zeithaml 1988). The price, promotion, and reputation of the company have a great influence on the customer in influencing the formation of a buying decision. It was explained that the more competitive the price given by the seller, the greater the purchasing decisions made by the customer. Likewise, with promotions, the more intensive and attractive promotions that are held will increase the probability of consumer decisions to buy them and a good assessment of the company is also one of the factors that can influence the formation of purchasing decisions. This is because consumers will always look for companies that provide a specification in accordance with what this is expected by consumers (Ayu 2019). Buying decisions made by potential buyers are not always direct purchasing decisions only but also pending purchase decisions. One of the reasons is that funds are not yet available for purchase (Kim et al., 2008; Anggraeni et al., 2020). When prospective buyers have an interest in a particular product and already have a trust in the seller's account in question, then they will give a 'mark' on the seller's account or product.

CONCLUSION

COVID-19 pandemic give opportunity to evaluate consumers lifestyle choices. The purchasing decisions helped to contribute to the food, electronics, clothing and other industries which were sluggish because of the closure of shopping centres and the borders of social activities. There are also negative risks that must be faced by consumers during this pandemic, namely functional risk, financial risk, social risk, psychological risk, and time risk. They are also triggered by security problems, loss of payment checks, accumulation of bills, and uncertainty the store. Thus, companies should pay more attention to prices and set a competitive price in addition to the quality of services in accordance with the wishes of consumers, update their customer personas and communication strategy, and giving maximum quality of product and good performance.

ABSTRACT

The world is currently experiencing extraordinary event after coronavirus disease 2019 (COVID-19) first appeared in Wuhan, Hubei Province, China. This event is declared as a pandemic because it spread widely throughout the world including Indonesia. Indonesia has a *Work From Home* (WFH) system that is assumed ineffective because there are still many people who are unable to stop going to their office. They have economic limitations, so they also find it difficult to get personal protective equipment to avoid being exposed by the COVID 19 viruses. This study used qualitative analysis with data obtained from online questionnaires. The data obtained states that the Vending Machine Mobile is considered effective in solving problems. The Vendible has related to the difficulties of the public to access personal protective equipment to avoid being exposed to the COVID 19.

Keywords: basic personal protective equipment, COVID-19, Indonesia, Vendible

INTRODUCTION

Currently the world is experiencing extraordinary event after the Novel Coronavirus Disease (COVID-19) was declared as a pandemic by World Health Organization (WHO) on 30 January 2020. This virus was first discovered in Wuhan, Hubei Province, China in December 2019 and spread very quickly throughout China (Zheng et al., 2020; Putra and Abidin, 2020). In Indonesia, people infected on Nov 2019, and COVID-19 were first discovered on 2 March 2020 (CNN Indonesia, 2020a; Anggraeni et al., 2020). Based on the data obtained from Worldometers, the spread of this case takes place so quickly. On 19 April 2020, there were 6,248 cases in Indonesia, 535 of them died (CNN Indonesia, 2020b).

COVID-19 is an infectious disease caused by a newly discovered coronavirus. The COVID-19 virus spreads in the form of small droplets that are usually released by people who have been infected while sneezing or coughing (Rawan and Triwidiastuti, 2000). These droplets generally will not move but fall to the ground or a surface within a few seconds. This is the reason social distancing or physical distancing effectively prevents its spread (Sauer, 2020).

This virus spreads in the form of droplets released by the infected people (Maryanti et al., 2020). This virus will not move but fall to the surface. Social distancing or physical distancing is effective in preventing the spread of this virus. However, social distancing or physical distancing affects various aspects such as economic, social, and environmental aspects. Moreover, Indonesia is still a developing country whose economy is not as good as developed countries. In implementing the *Work From Home* (WFH) system, our society has difficulties because there are still many people who have to work to provide needs for their family.

Previous researches on COVID-19 stated that using masks or face masks during religious rituals to prevent the spread of the virus (Dong et al., 2020) are a must, and a tool or website to track COVID-19 cases in real time (Liputan 6, 2020) are needed. These two studies are different from our researches on Mobile Vending Machines (Vendbile) which can help distribute tools to prevent the spread of COVID-19 such as masks, hand sanitizers, and hand washes in areas that need these items throughout Indonesia.

This research answered some of the problem formulations including the socialization on the importance of COVID-19 prevention tools and systems to the society, how Vendbile works to the society, and how important Vendbile is for Indonesian. We conducted this research based on the apprehension we experienced because there are still many people who find it difficult to get tools such as masks and hand sanitizers to prevent COVID-19.

VENDING MACHINE MOBILE

Vendbile is one of the many ideas of transportation equipment that helps the government in distributing COVID-19 prevention tools (medicines, masks, hand wash, and hand sanitizer) using vending machines on an open truck. Illustration of a Mobile Vending Machine is presented in Figure 1.

Figure 1. Illustration of the Mobile Vending Machine design as a distribution tool for COVID-19 basic protective aid.

The distribution equipment proposed is presented in Figure 2. The tool is designed in three angles view namely, the front, left and right side, and backside as shown in Figure 2a, 2b, and 2c, respectively. Figure 2d shows the media used to explain the usage procedure of this aid distribution tool.

Figure 2. The visual appearance of the Mobile Vending Machine as a distribution tool for COVID-19 basic protective. Figures (a), (b), (c), and (d) respectively are the design of the device design from the front, side, back, and appearance of the media for the procedure to use the tool.

This tool is an automatic machine but it needs a driver, however, the driver still has to maintain physical distancing. Therefore, Vendbile is equipped with a guide written on the banners and small TVs in order to help people to know how to use it. People need to bring their identity cards, before using Vendbile apply hand sanitizer, scan the identity card, choose the desired items, and after getting the items, they applied hand sanitizer again.

RESEARCH METHOD

The research method used was a qualitative research method. Qualitative research methods emphasize data trends (Syandri and Akbar, 2020). This research took place during April 2020. The method in this study was a quantitative method with qualitative analysis and a questionnaire-based research method distributed online. After the information collected from a number of samples, information processed and analyzed qualitatively.

RESULTS AND DISCUSSION

This questionnaire form divided into two parts, the first part was the identity of the respondents, and the second part was related to the Vendbile. The second part consisted of 23 questions with one final question regarding suggestions and input for the further development of the Mobile Vending Machine in order to fit in with the COVID-19 prevention assistance standard (medicines, masks, and hand wash or hand sanitizer).

There were 180 respondents that answered the questionnaire which was distributed through social media.

Research showed that 75% of the respondents were female (Figure 3a). The most dominant respondents' age range is between 18-25 years (Figure 3b).

Most of the respondents' education level is a senior high school, followed by undergraduate and the rest were spread fairly evenly among the levels of junior high school education, diploma, and master degree (Figure 3.c). The majority of respondents worked as students (Figure 3d). The majority of respondents residing in West Java and many of them are from the city of Bandung, while other respondents came from various regions outside West Java, from Central Java, DKI Jakarta, and the rest were scattered in various regions in Indonesia (Figure 3e and 3f).

On the question of how the situation and condition in the environment around the respondent during the COVID-19 pandemic, the majority of people answered that it was in good situation and condition (Figure 4a).

Respondents who answered, mostly came from West Java, especially from the city of Bandung. The next question is about the respondents' understanding of the COVID-19 prevention procedure and the tools used. The majority of people understood it (Figure 4b). The result showed that the readiness and outreach based on information and messages disseminated by the government and the society have almost reached to all groups. The result of the next question is presented in Figure 4c. Respondents' opinions about the importance of standard protective equipment such as masks and gloves indicated that society has understood and considered this situation was important as well as the prevention of COVID-19. Out of

180 respondents, 138 respondents considered that the standard protective equipment was very important. Continuing from the discussion of the previous questions, it can be concluded that Indonesian people have had awareness in terms of basic prevention through the importance of using protective equipment such as mask and glove.

Figure 3. Identity of the 180 respondents.

Furthermore, the results in Figure 4d shows that majority of people (81%) only have masks as standard Personal Protective Equipment (PPE). This shows that the distribution of protective equipment was not evenly needed for the general public, especially those who live in West Java. Many factors could affect this, one of which is the limited access to transportation as a result the distribution only happens in certain areas.

Meanwhile, people's understanding of personal protective equipment produces data as shown in Figure 5, 176 respondents chose mask as the most important equipment. Some respondents also added other things that were also important such as disinfectant, glasses,

hazmat clothing, vitamins, herbal medicine, and jacket. Based on the response, we concluded that the society has already known items to prevent the spread of COVID-19.

Figure 4. Public opinion about the situation and conditions in the surrounding environment (a), understanding the prevention procedures and protective equipment from COVID-19 (b), public opinion about the importance of standard protective equipment (c), and ownership of standard protective equipment that reaches all groups according to the society (d).

In Figure 6a, 88% of the respondents had difficulties in obtaining protective equipment.

In Figure 6b, the information to be taken is the availability of PPE around society. 37% of respondents lived close to a place where information about personal protective equipment to prevent COVID-19 transmission could be accessed. The status of the PPE distribution showed that respondents still felt that the distribution had the Barrier, as shown in Figure 6c. Then in Figure 6d, survey results showed that the majority of respondents, did not feel the distribution costs to the society burdensome but the rest felt the government was burdening them with the costs.

Figure 5. Graph of the most important personal protective equipment for the society.

Figure 6. Difficulties of the society in obtaining personal protective equipment (a), availability of personal protective equipment in the environment around the society (b), public opinion regarding the obstacles in the distribution of aid equipment (c), and regarding the imposition of transportation costs for assistance (d).

Figure 7. Equitable distribution level of personal protective aid equipment from COVID-19.

In Figure 7, 49% of the respondents stated that there was still a lack of equalization of the prevention tools. It could be concluded that the majority of respondents still felt unsatisfied with the distribution and that there was still uneven distribution.

In Figure 8a, we obtained the results of the data that the society gave full support to if an attempt was made to provide the PPE distribution tools. It could be concluded that society really needed a tool to distribute PPE so that the tool would be easily accessed by society without having to wait for a long time. In Figure 8b, the respondents would put the people who needed it first. Hospitals that received PPE assistance well were government-owned hospitals, while private hospitals still had difficulties in getting PPE assistance. In urban areas, private hospitals still found it was very difficult to get PPE and also in rural areas (World Health Organization, 2020).

In Figure 9, data collection is related to the idea of developing a Mobile Vending Machine to help distribute the personal protection and prevention tools of COVID-19.

Figure 8. Respondents regarding the planned provision of aid distribution tools (Vendbile) and their impact on the distribution of distribution to the society (a) and the respondents' opinions in using Vendbile if it has been realized (b).

Figure 9. Graph the importance of Vendbile to the society.

Vendbible is important for respondents. According to respondents, these tools were sufficient to help the distribution evenly. The technical and procedures for using Vendbible according to respondents were quite clear. For respondents, Vendbible could be a good idea in the distribution of personal protective equipment. This shows that this idea received a positive response from society.

The next question was about Vendbible license to operate around society settlements. As a result, the majority of people responded that it should be based on the situation and conditions in the areas where it operates. Furthermore, regarding the availability of respondents to become volunteers who participated in supplying Vendbible stock, the majority of people answered that they were not willing to participate. The next question is about the availability of the society to participate in socializing Vendbible to the surrounding environment. It shows that the majority of people answered that they were willing to participate. It means that society is willing to participate in socializing Vendbible in order to help the neighborhood to get sufficient information about Vendbible.

Figure 10. Vendbible breakthrough for the society.

On questions related to the existence of Vendbible in their areas regularly that can increase the number of vehicles on the road and add a little pollution in the environment, the majority answered it depended on the situation and conditions.

This shows that it would be wise if we operate Vendbible based on the situation and conditions of the areas. Furthermore, according to the respondents, the right and effective time for Vendbible to operate was in the morning. This shows that the operation of Vendbible will be more precise and effective in the morning because most people do not have many activities in the morning so, if the Vendbible would operate in the morning it can make the distribution even.

In Figure 10, the majority of people answered that Vendbible was very good. This shows that Vendbible can be useful to help the society especially on the equal distribution of COVID-19 prevention tools, especially in the red zone and in the underdeveloped, remote, and outermost regions in Indonesia. Quoted from CNN Indonesia, East Nusa Tenggara Province, for example, requires 17 million liters of disinfectant containing chlorine, while, at present, South Sumatra needs 250 million ordinary masks and DI Yogyakarta Province still lacks 3.2 million PPE (CNN Indonesia, 2020; Worldometers, 2020).

CONCLUSION

From this study, we can conclude that currently the society is experiencing difficulties in obtaining COVID-19 standard prevention tools. This problem is caused by hoarding the standard prevention tools conducted by some people. Then, based on the respondents' answers, Vendbile is a good and effective breakthrough to assist the government in distributing prevention tools in order to make it more equitable. However, the operations must be based on the current situation and conditions in society.

ABSTRACT

Coronavirus disease 2019 (COVID-19) is an infectious disease caused by a new type of coronavirus namely severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The disease has spread to 118 countries and infected 119,179 people on Feb 2020. Indonesia is currently affected by the COVID-19 outbreak. This has an impact on the economic, social, and educational systems. In these conditions, the transportation system also needs attention. The distribution of drugs and rapid test equipment to rural areas during the pandemic is a serious barrier. The number of areas that still lack of health facilities has caused lower health care for the community, including the current handling of COVID-19, such as the rapid test tool in every public health center in Indonesia. One solution that can be provided from this problem is the provision of Health Truck to help provide health services to deal with COVID-19, especially rapid tests on areas where health facilities are lacking. The rapid test tools available on this Health Truck can at least help in handling COVID-19, so that the provision of health services in remote areas can be overcome.

Keywords: COVID-19, disease, coronavirus, transportation, health, rapid test

INTRODUCTION

The new type of coronavirus has started to become a concern of the world community after on January 20, 2020, health authorities in Wuhan City, Hubei Province, China, said three people died in Wuhan after suffering from pneumonia caused by the virus (Febrian 2020; Razon 2020). The disease is caused by a new type of coronavirus namely severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and the disease is named corona virus disease 2019 (COVID-19) by world health organization (WHO) (World Health Organization 2020).

Coronavirus is a large family of viruses that cause diseases ranging from mild to severe symptoms. Common signs and symptoms of coronavirus infection include symptoms of acute respiratory disorders such as fever, coughing, and shortness of breath. In severe cases, it can cause pneumonia, acute respiratory syndrome, kidney failure, and even death (Maryanti et al., 2020). The clinical signs and symptoms reported are mostly fever, with some cases having difficulty breathing, and X-rays show extensive pneumonia infiltrates in both lungs (Kementerian Kesehatan Republik Indonesia 2017).

In March 2020, Indonesia began to be affected by this disease and after World Health Organization (WHO) declared this disease a global pandemic. At present, 18 April 2020, 5923 people have been positively identified as having COVID-19, 520 people have died, and 607 people have successfully recovered (Halim 2020). The Health Service recognizes the lack of COVID-19 treatment facilities in all regions of Indonesia to closely monitor people from exposure to the SARS-Cov-2 virus. One of them is the lack of supervision regarding public health itself (Nugraha 2020). Therefore, in the midst of the COVID-19 pandemic, Faculty of Mathematics and Science Education at the Indonesian University of Education students are developing ideas related to transportation systems that are relevant for conducting health surveillance in areas with minimal health facilities. The proposed idea is a health care transportation media that can maintain and control public health during the COVID-19 pandemic, especially for conducting rapid tests. Rapid test is an initial screening method to detect antibodies, namely IgM and IgG, which are produced by the body to fight coronavirus (Nareza 2020). These antibodies will be formed by the body when expose to coronavirus. The rapid test system used is a door to door system, so that it can prevent people from crowding in large numbers in one place simultaneously.

This idea still requires data to support it. So, we conduct research through online media. The confidentiality of personal data sent is guaranteed and processed for this research purpose only. Transportation media are provided to help the community, especially during the emergency COVID-19 pandemic, which is in an area with limited health facilities.

METHOD

The method used was a descriptive method using a questionnaire. The questionnaire was designed in such a way and then distributed randomly through online media to various regions in Indonesia. The collected data used as the source of information needed to develop ideas about the health care transportation media that can maintain and control public health during the COVID-19 pandemic. The data was processed by analyzing each question.

RESULTS AND DISCUSSION

There were 221 participants participated on the online media questionnaire about the idea of the Health Truck to maintain and control public health, specifically to carry out a rapid test. The data shows various ages for both women (71%) and men (29%), from various backgrounds such as students, civil servants, entrepreneurs, teachers, and housewives.

Table 1. The number of participants in various regions

No.	Residential area	Number of Participants
1	West Jakarta	3
2	East Jakarta	3
3	South Jakarta	0
4	North Jakarta	0
5	Central Jakarta	0
6	Bogor City	6
7	Depok City	7
8	Cimahi City	12
9	Bandung	24
10	Tangerang City	0
11	South Tangerang City	0
12	Serang City	0
13	Cilegon City	2
14	Surakarta City	0
15	Cirebon City	2
16	Bogor Regency	25
17	Bekasi Regency	2
18	Bandung Regency	17
19	Subang Regency	40
20	Karawang Regency	1
21	Purwakarta Regency	2
22	Pandeglang Regency	0
23	Tangerang Regency	3
24	Other Areas	72

Based on *Table 1*, most participants were from the areas of West Jakarta, East Jakarta, Bogor City, Depok City, Cimahi City, Bandung City, Subang Regency. Meanwhile, participants were from other regions, such as Kutai Kartanegara Regency, Garut Regency. In this context, we only choose five regions with the most participants to be discussed, which are Cimahi City, Bandung, Bogor Regency, Bandung Regency, and Subang Regency.

Most of the participants were well aware of the dangers, symptoms, and prevention of COVID-19. Some participants chose to have their health checked into various health services while others choose to stay at home or do self-isolation and then had their observation after symptoms worsen (Putra and Abidin, 2020). In accordance with the circular letter submitted by the Indonesian government, if you experience some symptoms that indicate COVID-19 and people must stay at home to isolate themselves. In addition, people who appear to be healthy or fine are still encouraged to continue to take various precautions to reduce the spread of COVID-19 (Jogloabang 2020).

Based on Figure 1, participants who need a rapid test are those live in Cimahi and Bandung cities that are red zone area, as shown in Figures 1(a) and 1(b) require a rapid test, but they do not make this much of a problem because they assume that their area has already had adequate health facilities in handling COVID-19. Meanwhile, Subang Regency, Bandung Regency, and Bogor Regency which are shown in Figures 1(c), 22.1(d), and 1(e) are areas with a high percentage of needs regarding the handling of COVID-19, especially for rapid tests. This may be due to various factors, for example, in Subang Regency has a very large number of People under monitoring, but is also limited to the procurement of rapid test equipment (Firmansyah 2020). Therefore, people really need this health facility.

Figure 1. (a) Participants who need rapid tests in Cimahi City, (b) Participants who need rapid tests in Bandung, (c) Participants who need rapid tests in Bogor Regency, (d) Participants who need rapid tests in Bandung Regency, and (e) Participants who need a rapid test in Subang Regency.

Most of the participants (46.15%) stated that there were closest health services that could conduct COVID-19 tests, there were also participants (22.18%) who said there were no health services in their area, and the rest (31.67%) were participants who still doubted the existence of facilities in the area.

Based on the data obtained, the health services available in the participant area were mostly clinics, puskesmas, and hospitals. However, the procurement of COVID-19 tests at clinics and puskesmas was limited due to limited health facilities or a limited number of rapid test equipment. As many as 50.23% of participants stated that the community might experience difficulties in handling health, 32.58% of other participants responded that they did not experience any difficulties at all, and only 17.19% of participants stated that they

experienced difficulties in handling health. In fact, not all health services can handle problems related to COVID-19. One solution that can be provided from this problem is a health care transportation media that can maintain and control public health during the COVID-19 pandemic. Furthermore, in handling COVID-19, about 91.4% of participants needed special transportation to help with health management and control, then, only about 8.5% did not need it.

Figure 2. Distribution of needs for health facilities in various regions.

Figure 2 shows the data distribution of the needs of health facilities in various regions of Indonesia. Cimahi City, Bandung City, Bogor Regency, Bandung Regency, and Subang Regency are the regions with the highest number of participants. Based on Figure 2, Subang Regency is the area that most needs health facilities. Then, followed by Cimahi City, Bandung Regency, and Bogor Regency which are the COVID-19 red zone areas.

Therefore, to overcome the problem of limited health services, we propose ideas to participants regarding transportation media, namely Health Truck. Health Truck is a health care transportation media that can maintain and control public health during the COVID-19 pandemic. In the Health Truck, there are several health services, especially rapid tests needed by the community during a pandemic like this. In this Health Truck idea, we pay attention to various health service protocols, both for patients and medical personnel, provided by the government based on World Health Organization technical guidelines (World Health Organization 2020).

The shape of or designated Health Truck as can be seen in Figure 3, is a medium-sized car that has a futuristic look with various health facilities and personal protective equipment inside. The shape of the Health Truck is deliberately designed smaller than a truck so it can be driven on narrow roads.

Figure 4 shows the data of participants who supported our ideas. After the participants learned about the purpose and function of this Health Truck, most of the participants were very supportive of our ideas and hoped that this would be the solution to the existing health

service problems. Even after the end of the epidemic, this transportation can continuously be used, especially in remote areas that lack health facilities.

Figure 3. Health Truck design.

Figure 4. Participants who support the idea of Health Truck.

If this transportation media was built, most of the participants think that they would participate to take the test as long as it is free of charge. According to the participants, the Health Truck was also effective in preventing transmission of COVID-19, participants also stated that many areas or regions would need this Health Truck.

Based on the results of the questionnaire, participants revealed that there were still many needs of the community in the prevention of COVID-19 such as masks, hand sanitizers, disinfectants, Personal Protective Equipment (PPE), rapid tests and swab tests. The swab or RTPCR test results are more accurate than the rapid test. Therefore, swab test or RTPCR is important to ensure whether someone infected by the COVID-19 (Majni 2020).

CONCLUSION

Based on the method we carried out on 221 participants, it can be concluded that the majority of the community needs additional facilities to deal with the COVID-19 pandemic. Through our ideas in the form of Health Truck, it is expected that it can support the community in facing the COVID-19 pandemic.

ABSTRACT

Since the coronavirus disease 2019 (COVID-19) pandemic began to spread in Indonesia, the government has implemented several policies. Implementing physical distancing and encouraging workers to work at home and encouraging students to study at home are among those policies. Although this policy has been made, workers including medical personnel still have to work outside. COVID-19 has also impacted the workers' income and as a result, they find it difficult to meet their daily needs. Therefore, we designed an automatic box on a vehicle to distribute food aid to medical personnel and workers who do not work from home using the Drive-thru system. This drive-thru system was chosen because it is easy and supports government efforts in implementing physical distancing.

Keywords: drive-thru, automatic box, COVID-19, food transportation

INTRODUCTION

Coronavirus disease 2019 (COVID-19) is a disease that causes respiratory infections (Maryanti et al., 2020). This virus is a large family of coronavirus discovered after Middle East Respiratory Syndrome (MERS) and Severe Acute Respiratory Syndrome (SARS) (World Health Organization 2020; Anggraeni et al. 2020). This outbreak started in December 2019 in Wuhan, China, until it spread throughout the world and arrived in Indonesia in early March 2020 (Azanella 2020). The existence of this outbreak affects several aspects, one of which is the distribution of logistical needs. These are in line with government policies that require a reduction in outdoor activities. Most people have to work at home, but some still have working outside as the spread of COVID-19 continues to increase. Workers are losing their incomes and having difficulty meeting their daily needs (Putra and Abidin 2020).

Coronavirus affects those who make a living as private employees, laborers, and in particular workers in the informal sector. Many companies have laid off employees without pay. Although unofficial workers continue to sell their products, their income decreases due to limited community activities (Indraini 2020). Online drivers are affected by this policy as well as they lose up to 70% of their daily income. Besides supporting the family at home, they also need to pay for other needs, one of which is lunch (Media Indonesia 2020).

Another problem that arises is a large number of medical workers who are exhausted and need food aid to meet their food needs. Medical personnel in Banten claimed that the workload was getting heavier. The shift scheduled for four turns, and medical personnel who has the third shift scheduled, from 05:00 p.m. until 1:00 a.m., do not get food (Lesmana 2020). As known, the safety of medical personnel is not only a matter of the quality and sufficiency of Personal Protective Equipment (PPE) but also of the food to sustain the stamina. The medical personnel has to give a balanced diet and sufficient vitamins to secure their immune system (SeRiau 2020).

With this idea, there is a need to evolve ideas related to the appropriate transportation network to support the government's efforts to reduce the spread of COVID-19 by adopting the concepts of physical distance, yet to accommodate the food needs of those who are unable to work from home including medical personnel. The ideas that can be executed. Our proposed idea is to build automatic cars and motorbikes transportation.

In this case, the drive-thru systems in Indonesia has conducted by the One-stop Administration Services Office. Indonesian's drive-thru system is efficient to use and has received a strong response from society (Wardani and Rumiyatun 2017). Another innovation using the drive-thru system is the rapid test in Bogor city. Besides, Bogor city, Indonesia Ministry of Communication and Information also held COVID-19 RAPID test for media workers and employees. This action is part of an attempt to break the sequence of coronavirus spread. So, there is a need to develop the ideas related to the appropriate transportation network to support the government's efforts to reduce the spread of COVID-19 referring to the effectiveness of using drive thru in the previous case. RAPID Test are carried out with the drive-thru system in order to avoid crowds and conform to the coronavirus prevention protocol on physical distancing (Kontan 2020). The drive-thru system is used to prevent greater transmission (Kosasih 2020). Many countries still continue to use the drive-thru system during the increased spread of COVID-19 one of which is Spain. Spain ranks second with the number of positive patients reaching more than 136 thousand and deaths exceeding

13,341 as per Tuesday on 7 April 2020. Facing a growing number of deaths, Spain began to apply the drive-thru system for funerals (LPPM UM 2020). It inspired us to create concepts following the drive-through system.

AUTOMATIC CAR BOX AND MOTOR

Using a drive-thru system to distribute food to people who cannot work from home starting from the middle to lower class workers and medical personnel is a breakthrough. This mode of transport supports the physical distancing efforts being implemented by the government during the COVID-19 pandemic. The designed automatic car box and motorcycle box is used to distribute free food to people who cannot work from home and to medical personnel. Workers or motorists who will distribute the food aids do not need physical contact with the recipients, because they could take the food themselves through the gap/window box.

In general, the difference between a drive-thru system using a motorcycle and a car is on the target customers. The motorbike box is used for small-scale deliveries to homes/residential areas, while car automatic box is used for larger scales such as for medical workers, or people who cannot work from home as seen in Figure 1. The automatic box can be used both for motorbikes and cars. As for motorbikes, the box is placed on the back, fitted with an inner layer that can keep food fresh and is resistant to cold and hot heat. In addition, the box is spacious in order to maintain food condition. The food is put in the package from the back of the box, as shown in Figures 1a and 1b. The rationale for using a motorcycle is to make things easier for the courier to reach densely populated areas. The courier must also follow the protocol in compliance with government guidelines, such as the use of helmets and other protective equipment. Figure 1c. shows a box in a car. The idea of a car is very much like a motorcycle case, except the scale is greater and could carry more food. The courier will press the button to open the window. People can directly take food through without having physical contact with the courier. The food is hygienic because it is placed in another room. As soon as the food is taken, the new food box will appear automatically.

Figure 1. Automatic Drive thru box illustration. Figures (a), (b), and (c) respectively are automatic box illustration drawings on the motor from the "side" direction, from the "back", and automatic box illustration drawings on the car from the "side" direction.

Knowing that there is a large number of medical personnel who are exhausted and the declining income of people who cannot work from home, then this idea is created in order to help people who cannot work from home by distributing food aids for them. The food is free of charge. We believe that this idea requires feedback and suggestions so the concept would

be more effective and efficient. As a result, we conducted an online survey using the Google form targeted at various categories of people.

METHOD

The study was conducted online using the Google form on 17 April 2020 from 09:00 a.m. to 15.15 p.m. Forms made in questionnaires and distributed to different groups of people. The questionnaire consisted of questions relating to identity age, educational background, occupation, and the area of residence. It also had questions that matched the data needed to support this concept, as well as a comment section where the respondents could write recommendations.

RESULTS AND DISCUSSION

Questionnaire forms distributed through social media and 101 responded to it. Most respondents were in the age range of 16 - 25 years old. In the last education-related questions, more than half of the respondents were high school and undergraduate students. Knowing the respondent's education level was needed to predict their maturity in responding to the questionnaire given. Furthermore, most of the respondents were students, some of the respondents worked as civil servants, employees, and entrepreneurs. On questions related to residential areas, dominant respondents lived in West Java spreading from the city of Bandung, Cianjur regency, Bandung regency, Bekasi regency, Bogor regency, Majalengka regency, Subang regency, Cimahi city, Cirebon city, West Bandung regency, Sukabumi regency, Bekasi city, Bogor city, and Depok city. The respondents also came from outside West Java and Java.

There were 21 questions related to the data needed in developing the concept. On the final question, participants could write suggestions. On questions related to the condition and situation in their area, some respondents responded that the conditions and situation got better because the number of COVID-19 positive patients was less than in other regions. However, there were also respondents who felt that conditions and situations in their area worse because a number of COVID-19 positive patients were rising and many who lived in the Red Zone area still went working, because they had to support their families. On questions related to whether or not many communities around the area could not work from home, we found out that quite a lot of people could not work from home because they were still in the Green Zone area so they still felt safe.

We also found out that there were still quite a lot of people around the respondents who could not work from home such as online motorcycle taxi riders. Respondents' answers related to the question of whether or not the respondents knew about food aids from the government, half of the respondents had already known that the government provided food aids to the community.

On questions related to the equal distribution of food aids organized by the government, most respondents responded that food aids were not evenly distributed. That means not everyone who needed food aids was entitled to receive them.

The next question related to the need for food aids for people who cannot work from home and medical personnel, many respondents stated that food aids for them were needed because the salary that someone earns cannot be measured precisely. It means there were many who earned incomes but worried about what food to bring home for the family. Furthermore, on the question related to whether or not people who could not work from home and medical personnel found it difficult to get food aids, almost half of the respondents stated that food aids were difficult to get, but there were also people who did not know about the difficulty that medical personnel and people who cannot work from home experience in getting the food assistance.

For the question of what assistance needed by people who could not work from home and medical personnel, it was found that the majority of respondents thought they needed personal protective equipment (PPE), masks, and hand sanitizers as seen in Figure 2. We analyzed that people who cannot work from home and medical personnel needed these items because this pandemic requires everyone to be hygienic and clean to protect them from the invisible germs and viruses.

In the beginning, there was a panic buying phenomenon and some people hoarded these items. It can be concluded that this has caused difficulties for people to get PPE, masks, and hand sanitizers during this pandemic.

Figure 2. Data on basic needs besides food aids.

The next question related to the ideas of whether our design could be considered effective in implementing physical distancing, most of the participants answered that it was quite effective and none of them answered ineffective (Figure 3). It can be concluded that this idea could become a breakthrough in implementing physical distancing if it is executed. This idea is considered quite effective because it is quite difficult for people to maintain physical distancing due to urgent needs such as buying basic necessities.

The respondents were then asked to answer whether the government's food aids were given to the right person, and in fact, more than half the number of respondents responded that the government's assistance had not been given to the person who was entitled to receive

the aid. The next question, respondents were asked to state certain groups of people who need food aids rather than people who cannot work from homeworkers and medical personnel. Respondents gave suggestions that people who were entitled to receive food aids other than people who cannot work from homeworkers and medical workers were the poor, marginal people, people who had no income, middle-to-lower society, the elderly, traders, private employees, online motorcycle taxi riders, orphans, pedicab drivers, daily laborers, unemployed people, volunteers, workers laid off due to the COVID-19 pandemic, factory workers, farmers, homeless people, orphanages, tutors, beauty workers, homeworkers, overseas students, public transportation drivers, middle and lower workers, administrators at places of worship, and all Indonesian people who are certainly affected by the COVID-19 pandemic.

Figure 3. Data on the effectiveness of ideas to be realized by applying physical distancing.

The next question was asked to the respondent regarding whether or not the respondent knew the difficulties of people who cannot work from home workers and medical personnel in getting food, most of the respondents considered it was not difficult for them to get food. Respondents were also asked to give advice, what staple foods were needed and almost all respondents responded that the staple foods needed were rice, vegetables, side dishes, and fruits. A small number of respondents suggested that other food aids needed also include milk, vitamins, canned foods, and snacks. The next question related to the development of this idea on its effectiveness using a motorcycle, more than half of respondents answered effectively considering this idea prioritizes the principle of physical distancing to break the chain of COVID-19 spread.

Then, the next question related to the costs required whether the production would spend an excessive amount of money, some respondents stated that this idea required quite an excessive amount of money. Moreover, this idea is suspected to cause new problems because there may be a gap between recipients and non-recipients, so respondents are asked to comment on it. Most of the respondents agreed that there would be a gap between recipients and non-recipients, but some respondents believed that if this idea would be implemented in a respectful and equitable way then there would be no issue of social inequality between recipients and those who are not getting aid.

Furthermore, our design would be developed using bio solar as a fuel source. Almost all respondents thought it was possible to implement the use of bio solar, but there are also a small number of respondents who did not respond to this question. The respondents were also asked to address whether there might be hurdles to the distribution of food and to provide examples of what barriers could emerge. Respondents gave examples of obstacles that might occur, including distance, access to the area, road conditions, time, unequal distribution, corruption of food aid, food aid shortages, the goods capacity, physical contact, courier safety, and food delivery concerns exposed to COVID-19.

The last question was about the corruption of food aids which could have been found by respondents. More than half of the respondents had never seen any corruption in food aids committed by any individuals, but there were also respondents who often encountered corruption in food aids. The last data was the feedback where respondents could include ideas, feedback, and expectations that we could use to improve our design to be more effective and productive. The suggestions given by respondents include list of the eligible recipients, the impact on this idea to the community, fairness, and equity on the distribution, safety on the distribution, transparency on the distribution to prevent corruption, coordination with many parties, strict rules for couriers, and involve local community leaders.

CONCLUSION

Our idea is still possible to be implemented although it still needs to be re-examined since there are still many things that need to be considered and developed. This assistance is not only proposed for people who cannot work from homeworkers and medical personnel but is also needed for all people affected by the COVID-19 including middle-to-lower society as well as those who are unable to meet their daily needs. The community also hoped that the assistance provided would also include medical needs, financial assistance, and internet access for students and college students. The respondents also expect that this concept could be properly designed, fairly, on schedule, and uniformly implemented in order to reduce the issues or effects that might be created and would not create additional challenges for the community and would help the efforts of the government to socialize physical distancing.

ABSTRACT

The health crisis is happening in the world today because the number of infected people with coronavirus disease 2019 (COVID-19) continues to grow day by day. This happens because the virus that infects the respiratory system spreads rapidly. COVID-19 is transmitted by a droplet of an infected person. The world currently applies a social distancing to prevent the transmission of the COVID-19, including Indonesia. However, social distancing has impacted the economy, especially on the food access problem. Therefore, we carried out research aimed at developing ideas related to transportation systems for food fulfillment during the COVID-19 pandemic, which is the provision of Mobile Food Trucks. This research conducted using a quantitative method with a technique method of a survey by filling out the questionnaire online through the Google form application. The survey was responded by 259 respondents from the provinces of Banten, Jakarta, and West Java. The results of this study indicate that society indeed has difficulty in fulfilling its basic food needs in the middle of the pandemic due to the implementation of social distancing. The basic food fulfillment facilities currently available also do not fully fulfill the needs of the community. Besides, the survey results also showed that the public responded well to the idea of this Mobile Food Truck.

Keywords: COVID-19, food truck, social distancing, transportation system

INTRODUCTION

A mysterious case of pneumonia has reported in Wuhan, China, at the end of December 2019. A few days later, the virus that caused this disease has been identified and called coronavirus novel. (Anggraeni et al. 2020; Mulyanti et al. 2020). Corona virus is a type of virus that originates from animals and can infect the human body. This virus is very dangerous because it can cause death (Maryanti et al. 2020). This virus enters the human body through the nose or mouth and is transmitted through droplets. Data shows 66% of patients are related to a seafood market in Wuhan, Hubei Province of China (Huang et al. 2020). Recently, World Health Organization (WHO) has named this disease as coronavirus disease 2019 (COVID-19) (Perhimpunan Dokter Paru Indonesia 2020; Razon 2020).

Indonesia is one of the countries with a high spread of COVID-19. Quoted from the JHU Research Center website, Indonesia is among the countries with the highest spread of the COVID-19 in Southeast Asia with 5,923 infected cases as of April 17, 2020 (Johns Hopkins Coronavirus Resource Center 2020). The spread of the COVID-19 has led to many new policies made by the government. One of them is the regional quarantine policy which can help reduce the spread of the COVID-19. According to the European Centre for Disease Prevention and Control (ECDC), social distancing needs to be conducted because the COVID-19 is likely to spread through aerosols (Eurosurveillance Editorial Team 2020). Besides, social distancing is carried out to minimize the spread of the COVID-19 from infected to non-infected and aims to reduce the need for the health system. Besides, social distancing is the most effective treatment for those vulnerable to infection (Pfafftheicher et al. 2020, Maryanti et al. 2020). According to WHO in the Interim guidance issued on March 19, 2020, quarantine during the initial outbreak can slow the peak of the epidemic (World Health Organization 2020).

In Indonesia, regional quarantine has been implemented in several regions. Especially for regions with a high number of infected cases, such as Jakarta and West Java provinces, which have implemented Large-Scale Social Restrictions (LSSR) system for their residents. LSSR which is carried out as a social distancing movement does have a positive impact, that is, reducing the mobility of the community or helping to carry out social distancing to reduce the possibility of the spread of the COVID-19. However, social distancing also has significant social and economic impacts (Dalton et al. 2020). The economy can become unstable amid this pandemic situation (Center for Food Safety and Applied Nutrition 2020). These things certainly happen because of the limitation of community activities, this is what then moved us to make a breakthrough in the transportation system during the COVID-19 pandemic to facilitate access for the community. The breakthrough that we made was supported by the state of the community during the COVID-19 pandemic which required to stay at home since activities outside the home were limited.

People certainly needs to fulfill their basic needs, especially food fulfillment. The current conditions are quite impossible for people to go out routinely to fulfill their food needs because markets are usually visited by many people. Therefore, U. S. Food and Drug Administration in their article entitled Food Safety and the COVID-19 stated that we must follow four key steps for food safety which are clean, separate, cook, and chill to prevent foodborne diseases (Center for Food Safety and Applied Nutrition 2020; Machmud and Minghat 2020). Referring to the conditions mentioned earlier, we are trying to make a

breakthrough or a new idea in the transportation system that makes it easier for people to fulfill their food during the COVID-19 pandemic.

IDEA DEVELOPMENT

People need to fulfill their daily basic food needs; however, it is quite difficult to do during the COVID-19 pandemic. We developed a transportation idea during the COVID-19 pandemic named a Mobile Food Truck to assist people to provide food fulfillment during the COVID-19 pandemic in the LSSR areas in Indonesia. The idea of a Mobile Food Truck is the provision of transportation to help the implementation of social distancing where this truck will sell the needs of the basic food. This food truck will operate from house to house so that people can access food and also the foods are sold easily. This food truck operates from house to house in order to avoid direct contact with many people and minimize trading in the market. The basic foods sold are also obtained from market traders so that it can become a consideration for traders to participate in the success of LSSR. Basic foods that are sold in a food truck will not be touched directly by the buyer, the buyer only mentions items they want to buy and the seller will pick it up for the buyer. The buyer can also choose by pointing the desired items through the transparent glass on the Mobile Food Truck (Figure 1).

Figure 1. The illustration of food truck idea.

METHOD

We conducted a study on April 17, 2020, as a review to develop our ideas. We used quantitative data collection methods with a technique method of online surveys and questionnaire using the Google form application that contains several questions arranged according to the theme with several answer options. The data obtained then processed as a data source that could help in the development of our ideas. The questionnaire was distributed specifically in the provinces of Banten, Jakarta, and West Java in areas in the three provinces with a high COVID-19 case.

RESULT AND DISCUSSION

The total participants in this study using Google form were 259 participants, dominated by female participants. Participants who participated in filling this questionnaire were mostly in the age range of 16-20 years (see Figure 2a), and they are students. In addition, some participants were housewives and other occupations, as shown in Figure 3b.

Figure 2. (a) Participants age dan (b) participants status.

Most of the participants came from regions in Banten province, followed by participants from regions in West Java Province and participants from Jakarta Province. The distribution of participants' residence is presented in Figure 3. From the personal data filled in the questionnaire distributed via Google form, it could be concluded that most participants came from among students from the regions of Banten, Jakarta, and West Java Provinces.

There were twenty questions asked to the participants relating to the COVID-19 pandemic which then led to the theme of our study. From the questions filled in by the participants, different results were obtained. Based on survey data, almost all of the participants have known and understood physical/social distancing. Survey results showed that participants were people from areas where LSSR implemented. From the data obtained it could be concluded that the average community residing in the area of the implementation of the LSSR has known and understood about physical/social distancing which is the key to the implementation of the LSSR itself.

In this survey, we presented questions related to our ideas which would later be able to support the development of our ideas. We included questions related to the fulfillment of basic food needs in participants' respective home areas during the COVID-19 pandemic. Survey data showed that most participants had no difficulty getting food during social distancing (see Figure 4a). The participants were the people who fulfilled their basic needs (mainly basic food needs) by going to markets and supermarkets. Then, although social distancing had been applied, most participants still went to the market occasionally, even some participants still routinely went to the market as shown in Figure 4b.

The types of the most needed basic food during the COVID-19 pandemic according to the survey results are presented in Figure 5. Participants could choose more than one option provided and rice was the most needed basic food according to the participants' choices, followed by vegetables, herbs, and other basic food needs.

Figure 3. The Distribution of participants residence.

Figure 4. (a) Participants difficulties in fulfilling food and (b) intensity of participants going to the market.

Figure 5. Participants basic food needs.

Although many participants still went to the market, most participants admitted that there was fear of going to the market during this pandemic. Most participants also admitted that it was not conducive to go to the market in the middle of this pandemic. Almost all participants were concerned about physical contact with many people when they were going to the market. Participants were also worried about food conditions that were openly displayed in the markets and had direct contact with many people (see Figure 6a). The market situation in the residence of most participants has slightly reduced visitors although it was still categorized as a crowded condition. Besides, participants responded to some difficulties in meeting basic food needs during the COVID-19 pandemic. One of the main difficulties was because some traders closed their shops, which then led to difficulties in fulfilling other basic food needs encountered by participants. Therefore, it could be stated that the implementation of social distancing, or in general the implementation of the LSSR in the residence of the participants are related to one another. Other than that, there were other difficulty factors explained by the participants, i.e., the lack of public transportation, supplies that were running out (especially in stores), and some of the participants explained because of the fear of leaving their houses as shown in Figure 6b.

Figure 7 shows the fulfillment of the basic foods of the participants if they did not go to the market. They mostly bought basic food needs at a shop near their homes. Besides, participants also chose delivery and waiting for peddlers as an option to fulfill other basic food needs. However, according to more than half of the participants, options such as food shops near houses and peddlers could not fulfill all the basic food needs of participants. Delivery options also could not fully help in fulfilling the participant's basic food needs, because according to the participant's explanation some shops did not have delivery services, making it difficult for participants to access. Some participants also explained that it was not uncommon for participants to have stored food supplies at home. However, afterward, the data was obtained that most participants felt worried that some of the stored food supplies were no longer fresh and would be stale and then wasted.

Delivery and peddlers were the options of the fulfillment of basic food needs during this pandemic that were mostly chosen by participants. The data obtained also showed that participants responded well that delivery and peddlers helped fulfill food during the COVID-19 pandemic. Some participants also responded related to peddlers, the intensity of peddlers in the participants' residence was reduced during this pandemic. Besides, from the survey data, it was found that most participants were worried about the food conditions that peddlers sold were openly displayed.

In this questionnaire, we included several questions that were directly related to the ideas we had in order to see the communities' response to our idea. The data obtained from these questions could later be used as suggestions/input. We presented our ideas related to the transportation system during this pandemic. Most of the participants responded well to our idea by assuming that this food truck idea could be a solution to reduce the difficulty of the community in accessing food during LSSR. Participants also responded that the most appropriate time for a food truck to operate in areas affected by LSSR was in the morning and operated three times a week.

Figure 6. (a) Percentage of Participants Concerns About Physical Contact and (b) Participants Difficulties in The Fulfillment of Basic Food.

Figure 7. Sources of the food fulfillment if participants did not go to the market.

CONCLUSION

From all the survey data obtained, it could be concluded that the community indeed experienced difficulties in fulfilling basic needs during this pandemic. The problem in fulfilling food at the current pandemic is due to the limitation of citizens' activities with the implementation of LSSR in some areas. Facilities to fulfill basic food needs such as peddlers, food shops close to community houses also have shortcomings, that is, not all basic food needs could be obtained from these facilities because the citizens usually buy more complete basic foods by going to the market. The community's concern to leave the house and the condition of food that is displayed openly is also a problem. Food that is left open is feared to be contaminated by COVID-19. Then, judging from the participants' situation and response, the idea of a Mobile Food Truck that transports basic food could be a solution to the fulfillment of the needs of the basic food of the community during the COVID-19 pandemic, mainly in the area where the LSSR is implemented.

ABSTRACT

This research was conducted as an effort to reduce the spread of coronavirus disease 2019 (COVID-19). One of the efforts here is in the form of an idea to spray disinfectant using a mini helicopter. The background of this research is from the fact that current prevention of COVID-19 the spread conducted is still considered to be less effective. Although the government has now appealed for social distancing, there are still many people who do not understand the urgency of social distancing so that the number of COVID-19 cases continues to grow. Spraying disinfectants is also very necessary to eliminate viruses that stick to objects and viruses that are still airborne. Researchers have an alternative idea to spray hypochlorous acid periodically using a mini helicopter. This research was conducted using a survey method with the help of google form media. Based on the survey results, the research subjects argued that social distancing and spraying disinfectants became effective ways to prevent the spread of COVID-19. More than half of the research subjects stated that the idea of developing a mini helicopter for spraying disinfectants is possible to prevent the spread of COVID-19. The priority area for spraying according to research subjects is the COVID-19 the red zone area.

Keywords: disinfectant, hypochlorous acid, mini helicopter, social distancing, the spread of COVID-19

INTRODUCTION

Coronavirus is a type of virus from the corona viridae family that can infect the respiratory system both humans and animals. This virus is more commonly found in animals. The coronavirus was first identified in the 1960s. It was named Corona because of its body structure that looked like a crown (Verizarie 2020). The disease caused due to being infected with this virus is called COVID-19 (Maryanti et al. 2020). Coronavirus can cause mild disturbances to the respiratory system, severe lung infections, also death. This virus can affect anyone, both infants, children, adults, the elderly, pregnant women, and nursing mothers. This virus was first discovered in Wuhan city, China, at the end of December 2019 (Anggraeni et al. 2020). The virus is transmitted very quickly and has spread to almost all countries, including Indonesia, in just a few months (Merry 2020; Hasyim et al. 2020).

In March 2020, in Depok, Indonesia, there were two people affected by this disease. Then the spread was so fast that on 18 April 2020 there were positive cases of 19,248 people, 535 people died and 631 people were cured. The initial prevention steps set by the government to encourage people to work, worship, and study at home (BBC News 2020). It was quite effective to reduce mass gatherings. The next step is using a mask when leaving the house, washing hands with flowing water, maintaining physical endurance, and spraying disinfectants (Kevin 2005). Disinfectant in the medical view is a compound to prevent infection by destroying or dissolving pathogenic microorganisms by being imposed on non-living tissue such as operating rooms, operating instruments/medical devices, etc. In another sense, it kills germs, bacteria, and also viruses by destroying or dissolving them. This disinfectant is used in non-living tissues, such as equipment/rooms that want to be sterilized so that the disinfectant is currently used to sterilize rooms or other facilities (Vembi 2020).

Disinfection is prevention of various types of dangerous organisms, both viruses, bacteria, and fungi that can cause disease transmission. Spraying disinfectant is done to the aforementioned (Fathiyah 2020). Spraying disinfectants is often used on a person's body and WHO (World Health Organization) says disinfectants are dangerous if sprayed on the human body (Achmad 2020). Disinfectants that are sprayed on the body automatically will have accumulated harmful particles that are inhaled and enter the respiratory tract, either from detergents or alcohol (Aris 2020).

We developed ideas related to the transportation system to reduce the spread of COVID-19 in regions in Indonesia using mini helicopters. This idea still requires data from the Indonesian people, so we distributed questionnaires about our ideas for research purposes. It is hoped that this idea can be developed and be able to assist Indonesian people in preventing the spread of COVID-19. Our idea is to spray disinfectants using mini helicopters that can be used indoors or outdoors. This mini helicopter is equipped with a camera so that it can be controlled remotely. Spraying disinfectant not only by land but also through the air, this is done so that prevention of the spread of COVID-19 is more effective (Nanda 2020).

METHOD

The method used in this study was a quantitative method based on questionnaires. This questionnaire was designed in such a way and distributed to Indonesian territory through

social media so that data and information from the Indonesian people would be obtained. Questionnaires are data collection techniques that contain written questions to get responses from respondents. The data collected used as a reference in developing our ideas.

Our idea making a mini helicopter to spray disinfectant which is presented in Figure 1. This mini helicopter is small (mini), so it can be used indoors or outdoors. In the mini helicopter, there is a camera to see the surroundings, so it can be seen whether the situation is safe or not for spraying (Figure 2a). The mini helicopter is also driven by a remote control where the remote is controlled (Figure 2b). This helicopter also has a disinfectant liquid container and a tool for spraying the disinfectant. Spraying disinfectant could be easier especially at tall buildings using this mini helicopter.

Figure 1. Mini helicopter as disinfectant sprayer.

Figure 2. The situation around the helicopter can be seen through a monitor (a), the mini helicopter is also driven by a remote control (b).

RESULTS AND DISCUSSION

Based on data from 72 respondents on the questionnaire form that distributes, this idea is possible to be implemented. However, this idea has not been completely perfect. From this idea, we still have to consider other things. Most people believed that spraying disinfectants effectively reduces COVID-19 (Figure 3a). Spraying disinfectant was considered effective to prevent the spread of this virus because according to Juan Leon, a health scientist from Emory University, coronavirus is a virus that is covered with a protective fat layer which when exposed to disinfectants, the fat layer of the virus can be torn apart and make the virus weakened. Therefore, the use of disinfectants is recommended by a lot of scientists, especially to clean the surface of objects that are often touched by humans.

Figure 3. Spraying disinfectant is effective to prevent the spread of COVID-19 (a), it is necessary to spray in each area (b).

Spraying disinfectant in each area is needed to reduce the spread of COVID-19 (Figure 3(b)). Spraying of disinfectants is also done in places that have been visited by people with COVID-19. Spraying is conducted in an area where there is an indication that the patients exposed to COVID-19.

Meanwhile, spraying is also important in areas that have not been indicated by patients exposed to COVID-19 to reduce the spread of COVID-19.

The liquid used in spraying disinfectant is indeed safe and can reduce the spread of COVID-19 (Figure 4(a)). The disinfectant liquid is pulverizer at the right target, like at home, and the objects. It is not to be sprayed directly on a person's body because it can risk a person's health. Spraying disinfectant is done around the house (Figure 2(b)). The main priority in spraying this disinfectant is the object around the house. The part that needs to be sterilized is every surface of objects such as on door handles, toilets, and sinks. WHO does not recommend spraying disinfectants directly into the human body because it is dangerous. Alcohol or chlorine that is sprayer on the human body will not kill the virus that has entered the body but can be harmful if the alcohol and chlorine that is sprayed, are exposed to clothing or mucous membranes such as the mouth and eyes.

Figure 4. Disinfectant liquid is safe (a), and the part of the house that should be sprayed (b).

In the midst of this pandemic, a lot of Indonesian people have tried to anticipate the spread of COVID-19. Their efforts are like finding out or increasing knowledge about COVID-19 and ways to protect themselves from being infected by the virus. Many Indonesians already know how to make their own disinfectant liquid (Figure 5a). General knowledge about making disinfectants is certainly very useful for dealing with the current situation. Society can make their own forms of prevention without having to wait for government service. Therefore, this kind of knowledge is very important for our own good.

However, many people are still unsure about the safety of self-made disinfectants (Figure 5b). The public is also not entirely convinced that self-made disinfectants are effective in preventing the spread of COVID-19. This is because they do not know the ingredients that can be used to make disinfectants.

Regarding our idea of making a mini helicopter to help spray disinfectants in various regions, the results said that our idea could be implemented (Figure 6a). As if we implemented our idea in making this mini helicopter for spraying the disinfectant, around

56.90% of the survey results were willing to use it, while 31.90% of them still did not know whether they would use it, and the rest said they would not use it Figure 6b).

Figure 5. Lot of people can already make their own disinfectant (a), but there are still many who are not sure of the safety and effectiveness of the disinfectant that is made by themselves (b).

Figure 6. It is possible to develop mini helicopters for spraying disinfectants (a), and many people are willing to use mini helicopters to spray disinfectants (b).

Policies emerge due to the coronavirus outbreak can be seen with the closure of several access roads in a certain time, limitation on the amount of transportation, limitation on operating hours of transportation, which of course the policy is intended to be able to restrain the rate of society out of the house (Yunus and Rezki 2020). There are limitations to leave the house, therefore, the use of mini helicopters made unmanned to spray disinfectant on buildings and roads to reduce the spread of the COVID-19. This mini helicopter could be controlled from inside the building so that it still adheres to the government's recommendations to stay at home and reduce activities outside the home.

Based on the survey, around 42 people (58.30%) said that the fuel that should be used for this mini helicopter is solar power (Figure 7a), while others stated it would be better to use electricity. Another opinion said that we could use bioethanol or biogas fuel. It was suggested in order to maintain the environment and not adding a problem to the existing pollution. Hypochlorous acid can oxidize bacteria and other microorganisms in seconds and one of them is the coronavirus. Hypochlorous acid has anti-microbial, anti-inflammatory, and can also kill

E. coli bacteria in just 12 seconds. So, 59.70% of them said that spraying disinfectants using hypochlorous acid was an effective step in reducing the spread of COVID-19 (Figure 7b). But there are still people who do not know the benefits and functions of these fluids. There are still some people who consider that the liquid is not effective in preventing the spread of the COVID-19. In fact, by spraying the liquid, it could prevent the spread of COVID-19.

Figure 7. fuel that should be used for mini helicopters (a). effective hypochlorous acid (b).

Figure 8. Effective or not spraying disinfectant through the air (a). effective parts for spraying disinfectant (b).

Most people assume that spraying disinfectant through the air is still ineffective, also they still doubt whether spraying disinfectant would be effective (Figure 8a). The reasons are misconduct during the process which can endanger public safety. Therefore, when someone is spraying disinfectant through the air, it means that person must know the procedures. Spraying disinfectants is one step in preventing the spread of COVID-19, therefore, it is necessary to spray it in all areas. Especially areas marked by the COVID-19 red zone (Figure 8b) because these areas have a significant chance of COVID-19 transmission compared with areas that have been exposed to COVID-19 and areas that have not been affected by COVID-19.

CONCLUSION

This study concluded that this idea for applying mini helicopters is still very possible to be implemented. Most people think that spraying disinfectants using mini helicopters is possible and can reduce the spread of COVID-19. In addition, hypochlorous acid that does not contain alcohol can also be used as a disinfectant that can reduce COVID-19.

ABSTRACT

Coronavirus disease 2019 (COVID-19) pandemic has influenced several areas, one of which is transportation, specifically public transportation. This affected captive groups or public transport users, especially public transportation cars, as city transportation. The purpose of this study is to investigate public transportation problems during the pandemic and find out community responses in West Java regarding the idea of modifying urban transport. The method used is a quantitative method based on the questionnaire. The results showed how the transportation system of urban transport was not yet effective enough to prevent COVID-19 exposure at the moment. Respondents support the idea of the modification of urban transport as a solution with affordable fees and minimal modification costs. Respondents also approved the use of electricity as a fuel for urban transport and encouraged the government to execute the idea of a modification of city transportation.

Keywords: public transportation, modification, COVID-19

INTRODUCTION

Corona or COVID-19 virus pandemic has caused problems in various parts of the world, including Indonesia. COVID-19 is a new type of virus that attacks the respiratory system (Maryanti et al., 2020). The COVID-19 case in Indonesia has been announced since 2 March 2020 and has become increasingly epidemic. Indonesian government adopts a policy to issue health protocols implemented in all regions in Indonesia led by the Ministry of Health of the Republic of Indonesia (Kementrian Kesehatan Indonesia (Indonesia Health Ministry), 2020). Nonetheless, COVID-19 continues to expand and the number of infected people continues to increase every day. The speaker of the Indonesian House of Representatives repeatedly reminded the government to create a national team that would deal with the COVID-19 outbreak (CNN Indonesia 2020). Limited information causes the community worried and confused because they do not get safe and convincing services when they feel there are indications of exposure to COVID-19. Another problem that arises is the authority to determine public health emergencies by the central government or regional governments. The President of the Republic of Indonesia stressed that lockdowns should not be carried out, however, if the municipal leaders felt the need to carry out a lockdown in the area is allowed. The slow response of the central government and weak regulation have been seen as something obvious (Telaumbalua 2018).

The community demands that the government immediately handle the threat of COVID-19. The solution has been written in Law Number 6 Year 2018 on Health Quarantine about health quarantine and the determination of public health emergencies by the government. The rules are also laid down in the law as a follow-up to the provisions on health quarantine. Efforts are made to limit activities outside the home, stop school activities at school, encourage people to work from home and conduct religious activities at home. This has been a standard government strategy and has been optimally evaluated (Rezki and Yunus, 2020). These efforts have had an impact on various sectors in Indonesia, one of which is transport. Existing transport is not yet in a position to support the COVID-19 prevention protocol. As a result, people have difficulty traveling without worrying about being exposed to COVID-19. Therefore, we have the idea of modifying one of the public transport services in West Java, namely *minicab* by following the COVID-19 prevention protocol.

The general public group is divided into two groups, based on users of transport services, namely choice and captives. The choice group is a private vehicle user group, while the captive group is a public transport user group (Siswoyo 2008). Although some stay and work at home, the community (captive group) still needs public transport to work or purchase daily needs. As a developing country, most people in Indonesia are from the lower middle class (Siswoyo 2008). Lower middle-class people commonly use public transport. Public transport, which promotes the use of the COVID-19 prevention program, is therefore needed to facilitate the public's need for public transport.

Public transport cars, commonly referred to as *minicab* or *angkot* (in Indonesian language), are chosen by the community to travel long and short distances. The distribution is fairly even and reaches different regions at a relatively affordable cost compared to other public transport services. *Minicab* has a flexible pick-up point for passengers and can carry around 10-12 people. These advantages make *minicab* dominates West Java transportation and can be accessed by all groups (Sutandi 2015). It is also the type of public transport mode

that can be used as an alternative to public transport on the shortest, fastest and cheapest route. (Hobbs 1995; Hasyim et al., 2020). On the basis of these criteria, *minicab* is appropriate as a solution to the problems of public transport during this pandemic.

Figure 1. Illustration of exterior appearance (a), inside-front display (b), and inside-rear display on the modification of city transportation (c).

However, *minicab* modification is needed to prevent the spread of COVID-19. Illustration of changes in urban transport is shown in Figure 1. The modifications and background of the *minicab* selected are as follows.

1. Access to and from public transport is fairly simple, so that a body temperature thermometer can be installed before entering public transport (Figure 1a).
2. *Minicab* has a strategic area that can be modified to provide facilities/access to personal protective equipment. Automatic hand sanitizers can be supplied outside the *minicab* (Figure 1a) while masks are provided inside the *minicab* (Figure 1b).
3. Payment can be both digital and physical money. Money is one of the media which can spread COVID-19. *Minicab* can be equipped with digital wallet to prevent the spread of the virus through money. Payment can be made by scanning the QR code found on the *minicab* door (Figure 1b). However, *minicab* also accepts payment physical money, so that it is flexible in terms of payment.
4. The structure of the *minicab* is fairly simple compared to other four-wheeled public transportation modes. This facilitates surface sterilization of objects in public transportation (Figure 1b and 1c)
5. *Minicab* has good double-sided window air circulation (Figure 1c), to minimize the COVID-19 virus spread.

6. The distance between passengers can be easily adjusted by separating the position of the passenger seat and making it simple (Figure 1c).
7. In order to support physical-distancing efforts, the capacity of passengers is limited to 8 people by placing an X sign on the seats that cannot be occupied (Figure 1c).
8. The *minicab* pick-up points are flexible so that they can reach different regions.
9. Affordable price.
10. In addition to transporting passengers, *minicab* can carry a large quantity of food, such as sacks and boxes.
11. Modification of *minicab* requires only a small level of money and is prolonged.
12. The modification of *minicab* provides for public transport by preventing the spread of COVID-19. This solution uses active transport in West Java, so it does not cost money to create a new type of transport.

METHOD

A study was conducted in April 2020 with the implementation of the COVID-19 Distribution Prevention Protocol. The method used in this study was therefore a quantitative method based on a questionnaire. Questionnaire is a technique of collecting data through forms containing questions submitted in writing to a person or group of people to get the answers, responses, suggestions, or criticisms needed by researchers. Google form used to collect questionnaires. In addition, the literature review was also used to enhance references. Distribution of the questionnaire to all regions of West Java.

RESULTS AND DISCUSSION

The respondents were 54 people with the distribution of residential areas shown by Figure 2. The questionnaire was distributed with most of the respondents living in Cimahi, Bandung, and West Bandung Regency. The rest of the respondents lived in Depok, Cilegon, Purwakarta Regency, Sukabumi, Bogor, Garut Regency, Kuningan Regency, Sumedang Regency and Cirebon.

Each region has a different policy for public transport operations during this pandemic. Public transport was restricted as an effort to prevent the spread of COVID-19. Large numbers of public transportation have the potential to increase COVID-19 transmission (Kompas 2020a). Based on the results of the study, there were six modes of transportation chosen by the community during this pandemic, namely motorcycle taxi, taxi, train, bus, *minicab*, and pedicab (Figure 3a). The three modes of public transport most commonly used by the community are motorcycle taxi, taxi and *minicab*. All three of these transports underwent a dramatic change during this pandemic.

Motorcycle taxi still operates even though the operation is restricted by Pembatasan Sosial Berskala Besar (Large-Scale Social Restriction) rules in West Java. The Large-Scale Social Restriction (LSSR) rules state that a two-wheeled vehicle carries a maximum of two people living in the same house, as proven by their identity cards. In the meantime, both *minicab* and a car taxi could only carry 50% of their passenger capacity and are required to

limit the distance between passengers (Kompas 2020b). The use of masks is mandatory when traveling during the LSSR. This is certainly a challenge for public transport operations.

Figure 2. Distribution of respondent's residence in West Java.

Figure 3. Public transportation in West Java, Indonesia: (a) active and (b) operation.

A balance between the quantity of supply or unit and demand is needed in public transport operations (Juanita and Pinandita 2016). The call to stay at home and work from home (WFH) has an impact on current demand, resulting in a decrease in the number of passengers (Anggraeni et al., 2020). The decrease in passenger numbers has resulted in a decrease in public transport units (Figure 3b). In addition, several regions have issued policies so that public transport does not operate.

Efforts to protect passengers from exposure to COVID-19 in public transport may be made by passengers themselves or by an authorized institution to change the transport system. Passengers can use masks and apply hand sanitizers. These things are very simple, but in fact, there are still some people who are negligent in their implementation. Such negligence can increase the chance of being exposed to COVID-19 while on public transportation. However, the possibility of the negligence of users of public transportation can be anticipated by providing access to masks and hand sanitizers on public transportation.

The Indonesian Transportation Agency has changed the transportation system to support the prevention of the COVID-19 spread. Broadly speaking, public transport policies are limiting distance between passengers (physical distances), reducing the number of passengers to support distance restrictions, periodic sterilization of public transport surfaces, and reducing operating time due to reduced passenger volume. Body temperature measurements

before entering public transport are also carried out to minimize contact with symptomatic people with COVID-19. Although these efforts have started to be socialized, not all public transport implement them. Based on the results of the questionnaire, *minicab* has not yet implemented overall preventive measures (Figure 4). This shows that *minicab* is vulnerable to COVID-19 exposure. Although such efforts have been done, respondents felt normal with the changes in the current public transportation system (Figure 5a). On a scale of 1-5, the majority of respondents are satisfied on a scale of 3. This is caused by prevention efforts that are not carried out in an optimal and thorough manner. On the other hand, the respondents assessed that efforts to prevent *minicab* from COVID-19 are still not effective in their implementation. (Figure 5b). Therefore, *minicab* modification to support efforts to prevent the spread of COVID-19 is needed to minimize the chance of COVID-19 exposure.

Figure 4. Changes in the city transportation system in West Java during the COVID-19 pandemic.

Figure 5. Satisfaction (a) and effectiveness (b) of the changes in the transportation system. Scales 1 to 5 are for dissatisfied to very satisfied, respectively.

Figure 6. The idea in modifying public transportation.

Based on Figure 6, the public welcomed the idea of modifying public transport. Respondents indicated that the modified *minicab* could reduce the spread of COVID-19. In addition, modified public transportation routes need special attention in order to be able to reach areas effectively, especially the PSBB zone and the red zone of COVID-19. The cost is expected to be affordable and modifications can be mass-produced. The community also supports the idea of using electricity as a modified public transport fuel. The idea emerged from public awareness of the impact of fuel transport on comfort, health and the environment. In addition, the use of electricity as fuel in public transport, in particular public transport, is a step towards a sustainable transport system (Sutandi 2015). The use of electrical energy will minimize air pollution caused by gasoline-fueled public transport. The community also supports this idea to be executed by the government.

CONCLUSION

Public transportation modification is needed as an effort to reduce the spread of COVID-19 in West Java, Indonesia. The modification maximizes self-protection from COVID-19 exposure by providing access to self-protective equipment and implementing physical distances, thereby reducing public concerns about travel by public transport. The community welcomes this idea with a condition that it has an affordable price and the modification is done as efficiently as possible. The public will also welcome the use of electricity as the *minicab* fuel and encourage the government to execute the idea of the *minicab* modification.

Chapter 444

MICROFLUIDIC DEVICES IN PCR SYSTEM FOR THE APPLICATION OF COVID-19 RAPID DETECTION

Budi Mulyanti* and Roer Eka Pawinanto

Department of Electrical Engineering Education, Universitas Pendidikan Indonesia,
Bandung, Jawa Barat, Indonesia

ABSTRACT

The aim of this study was to review the development of microfluidic devices in the Polymerase Chain Reaction system for the application of corona virus disease 2019 (COVID-19) rapid detection. Materials used for microfluidic devices are briefly reviewed as well. Clear descriptions for every microfluidic device, namely micropump, microvalve, and micromixer used to develop the whole Polymerase Chain Reaction system are discussed in detail, including their advantages and disadvantages. It is concluded that much progress has been achieved in the microfluidic-based on the Polymerase Chain Reaction system. The future benefits of this review are to encourage the microfluidic involvement within the Polymerase Chain Reaction system, especially for the application of COVID-19 rapid detection.

Keywords: COVID-19, microfluidic, micropump, microvalve, micromixer, PCR

INTRODUCTION

Since World Health Organization (WHO) on 11 March 11, officially stated that the corona virus disease 2019 (COVID-19) had become a global pandemic (Anjorin 2020; Anggraeni et al. 2020)), numerous countries all over the world have declared emergency state and shutdown public areas. Public areas have enormous potential for transmission of COVID-19 (Hasim et al. 2020). COVID-19 is a disease that is dangerous and can infect the human body. This disease is caused by a corona virus. This virus is transmitted through droplets

* Corresponding Author's Email: bmulyanti@upi.edu.

(Maryanti et al. 2020a). The mouth or nose is a bridge for the virus to enter the human body. The very small size of the virus makes it easier for the virus to enter the human body (Maryanti et al. 2020b). Diagnostic tools can play a significant role to decrease the spreading rate of the virus. Polymerase Chain reaction (PCR) is one method that can be used as COVID-19 rapid detection. Since many microfluidic devices can be used for PCR application and rapidly identify the virus then make the microfluidic has the potential to offer an affordable point of care (POC) diagnostic.

In the recent decade, microfluidic has been particularly attractive for medical applications such as drug transportation, polymerase chain reactions (PCR), and chemical detection. Many devices in microfluidics can be integrated with one another such as on a single chip that can speed up biological analysis, reduce samples and reagents, and thus provide solutions for the medical field. PCR becomes a key process and a powerful tool in genetic investigations, clinical diagnostics, and the forensic field. Besides, currently, the PCR method is one of the techniques used for COVID-19 detection. Therefore, the role of microfluidic becomes more important and urgent because of its benefits such as rapid detection, few samples, short analysis time, good sensitivity, and disposable.

The advantages of micro-sized PCR devices have been widely studied by many researchers. Initially, the room-based PCR chip was introduced by Kopp (Kopp et al. 1998). The PCR chip model provided the basis for further development, and to date, they have been duplicated by many other researchers. The PCR chip transition from simple microfluidic components to advance integrated systems is still ongoing. Some microfluidic parts for several purposes such as sample preparation, DNA/RNA amplification, and sample detection can be integrated on a single chip (Cady et al. 2005). Micropump, microvalve, and micromixer successfully provide a higher level of integration and allow more than one sample to be run in parallel, which can reduce the analysis time.

Various progresses on the development of magnetic nanomaterials for micromixer has been reported. One of the reports presented a classification of micromixer divided into four types according to drive modes, such as external permanent magnet, electromagnet, micro stirrer, and the integrated electrode (Chen et al. 2017). Jeong et al. presented a report on micromixer based on its applications (Jeong et al. 2010). They classified the applications of micromixers into three categorized such as chemical applications, biological applications, and detection. Meanwhile, Au et al. presented a report on microvalves and micropumps for Bio-MEMS (Au et al. 2011). However, all previous reports were still too general in studying the detection process using the PCR system based on microfluidic devices.

Therefore, in this study, we reviewed the development of microfluidic devices in the PCR system for the application of COVID-19 rapid detection. Materials used for microfluidic devices are briefly explained as well. Furthermore, here explains the advantages and disadvantages of these functional components which indicate that micropump, microvalves, and micromixer technologies have played an important role in the development of integrated microfluidic chips.

MICROPUMP FOR PCR APPLICATION

Several types of micropumps have been designed and fabricated with various structures and operating mechanisms. In general, micropumps for fluid pumping in PCR chips can be divided into two categories, namely: mechanical micropumps with moving parts and non-mechanical micropumps without mechanical components (Au et al. 2011).

In 2017, one group of researchers has succeeded in developing a peristaltic pump integrated into the PCR chip (Alam et al. 2017). 3D printing using VEROTM photopolymer materials was used to fabricate the micropump. Utilization of 3D printing technology allowed for relatively short fabrication time. The minipump design is based on the concept of a planetary gear and worked in the same way as a typical benchtop peristaltic pump. The micropump was able to pump fluids between 40 mL/min and 200 mL/min and continue to work well at a back pressure of 25 kPa. Therefore, this performance showed successful interfacing between chip and device where the conceptual polymerase chain reaction (PCR) chip is fabricated well without leakage or flow disturbance in the microchannels (Alam et al. 2017).

Figure 1. Magnetically-driven fluid flow. (a) As the motor rotates, (b) The cyclic magnetic pump comprises. (c) Sample filtration is driven by a pressure drop across the size-based filter (Liu et al., 2017).

In the same year, another group of researchers developed diafiltration-on-chip microfluidics integrated with magnetic peristaltic micropumps (Liu et al., 2017). The integration of magnetically driven peristaltic micropumps has the role of achieving a continuous flow of recirculation as shown in Figure 1a. This pump is operated using a three-dimensional microfluidic architecture, where magnetic material (iron filing) is joined into the layer above the flow channel which is divided from the flow channel by PDMS thin layer (Figure 1b). The filings of the iron are pulled down because the magnetic field deflecting the PDMS membrane and compressing the flow channel when a fixed magnet located below the flow channel separated from the sample by glass slide (Figure 1b). When an external magnet is moved in a plane along a flow channel, the place of this pressure in the channel moves with

the magnet and forces the fluid to move in the direction of the magnet's movement, which is similar to a peristaltic pump. The on-chip magnetic pump promotes steady flow through permeable membranes and high-resistance microfluidic pinch channels. Flux across the membrane is controlled by the relative resistance of the pinched channel and the membrane (Figure 1c).

Furthermore, Li et al. developed passive micropump which can produce and transmit microdroplets inside a microchannel with several millimeters' length in a much longer periode (Li et al. 2018). Passive micropumps can consistently carry large volume (more than 2000 μL) of fluid/oil microdroplets inside 3D spiral microchannel (4 m long and 2 cm high) in 8 hours of the period. The droplet flow rate can be easily adjusted by changing the quartz capillary parameters connected to the microchannel ends. This passive micropump was successfully applied to the home-made setup of droplet-based surfactant-free quantitative PCRs using only two syringes for droplet generation, a Teflon tube for PCR amplification and single thermostatic heater for a thermal cycle with the amplification efficiency of the virus reaching 91% of commercial PCR thermocycler (Li et al. 2018).

MICROVALVE FOR PCR APPLICATION

The completely integrated microfluidic system such as lab-on-a-chip (LOC) or a micro total analysis system (μTAS) cannot be realized without microvalve development (Vilkner et al. 2004; Dittrich et al. 2006). Therefore, microvalve becomes one of the most important components to be successfully applied to the compact integrated on-chip PCR microfluidics. In general, microvalve can be classified into two main types: active microvalve and passive microvalve depending on mechanical or non-mechanical moving parts.

Generally, the deflection of the PDMS membrane is utilized to interrupt the flow in pneumatic microvalve. This easily integrated with standard soft lithography process caused pneumatic microvalve to become one of the common valve architectures. Liao et al. developed a miniaturized RT-PCR system for the diagnosis of RNA-based viruses, in which the reagent and sample flow were controlled automatically by utilizing two micropumps and one microvalve, as shown in Figure 2. The fluid flow could be effectively interrupted when the pneumatic microvalve was closed, and the pressure of 69 kPa could cause the microvalve to close the flow of a fluid moving at $\sim 30 \mu\text{L}/\text{min}$ (Liao et al. 2005).

Manual microvalves system with 8 integrated channels for controlling up to 8 different flows of agents was developed by Lee et al. (2020). The working principle of the valve is based on flexible materials (PDMS) and mechanical structure. The plasma etching technique was used to bond 100 μm thickness of PDMS film fabricated on top microchannel. The mechanical structure for closing and opening the flow valve was integrated with two components. Firstly, the second slab of Plexiglass is fixed by a screw with 3 mm of diameter and width 0.5 mm of the thread pitch. Secondly, the screw hole is bigger than the PDMS piece (2.5 mm) make the PDMS piece move freely in this hole. The microreactor ($\sim 5 \text{ L}$ of volume) and multi-liquid mixing component is successfully connected by the valve system. The function of controlling liquid flows to the microchamber was effectively succeeded in using this valve system (Lee et al. 2020).

Figure 2. Schematic diagram of two-step micro RT-PCR chip integrated with two micropumps and one microvalve for controlling biosample transportation (Liao et al. 2005).

Figure 3. 3D schematics of a controlled-release microchip and a single anisotropically etched sacrificial membrane burst microvalves (Santini et al., 1999).

The other microvalve principle utilizes a sacrificial membrane. This concept introduced by Robert Langer which designs a silicone-based “drug-release” microchip containing etched cavities capped with the sacrificial” gold membrane (Figure 3) (Santini et al. 1999). The drug-containing solutions are filling the cavities prior to being sealed with the membrane. The electrical supply of 1volt was used to electrochemically dissolve the membrane. Therefore, the release of one dose (25 nL) of “drug” for every cavity is controlled by a voltage pulse. Meanwhile, Moreno et al. (2010) and Allain et al. (2010) reported the sacrificial membrane composed of silicon nitride and SU-8. When electrical current or the heat is applied to the sacrificial membrane, the microvalves are open. The debris from the disintegration of the sacrificial membrane can be released into the fluid (Moreno et al. 2010; Allain et al. 2010).

Baek and Min investigated microvalves for selectively extracting nucleic acid from bacteria and viruses by physical adsorption and beat beating (Baek and Min 2015). The principle work of microvalves in the chambers is to switch between the packed bed for the pathogen concentration and beat beater. Meanwhile, Zahra et al. presented the microfluidic system integrated with temperature actuated microvalves. The “open” and “close” position of

the valve is depending on the electrical supply to the heater. The atmospheric pressure obtained inside the chamber (microvalves) when there is no electrical supply. On the contrary, the temperature inside the chamber increases when the electrical supply is given and the generated pressure pushes up the valve membranes, which close the channel. The temperature of 92°C with an applied voltage of 4 V is given when the complete closure of the channel happened without liquid leakage. Furthermore, the time constant of the valve during the opening is 1.40 s (Zahra et al. 2015).

Tang et al. (2019) presented the multi-way microvalves with a rotor. The principle operation is based on a rotary mechanism. The five-degree rotational symmetry was obtained with a compressible rotor and a complementary stator seat valve. The Viton elastomer is used for a rotor to provide a seal and switch between outlets. The microvalves can be operated in two ways, including manually or automatically. The switching torque of below 0.03 Nm and the pressure of 370 kPa with no leakage is obtained by the microvalves (Tang et al. 2019).

Figure 4. Working principle of the microfluidic passive valve. (a) Concept structure of the valve. (b) Schematic valve actuation under pressurized liquid (Zhang et al., 2019).

Meanwhile, a high flow rate control under an ultra-low threshold pressure was realized through microfluidic passive valve comprising of a fluid chamber, a flexible membrane, and an ellipsoidal control chamber by Zhang et al. (2019). The UV laser-cutting and 3D printing technologies were used to fabricate the microvalves. The constant flow rate of 4.03 mL/min, with a variation of $\sim 4.22\%$ under the inlet liquid pressures varied from 6 to 12 kPa was achieved by the passive microvalves. Furthermore, the microvalves could stabilize the flow rate of liquid under the time-varying sinusoidal pressures or the square wave pressures (Zhang et al. 2019).

MICROMIXER FOR PCR APPLICATION

Besides the microvalves and micropump, the micromixer is often another important and necessary component in an integrated PCR microfluidic system. In general, two basic principles are followed to generate mixing at the microscale: passive micromixing and active micromixing. Passive micromixers do not require external energy, and the mixing process relies only on diffusion or chaotic advection. For this micromixing means, the flow energy due to pumping action or hydrostatic potential is used to rebuild a flow in a way that causes faster mixing. Active micromixers use energy input from the exterior for the mixing process.

These external energy sources include electrokinetics, acoustics, magnetohydrodynamics, integrated microvalves/micropumps, and others.

The simplest micromixer structure is Y/T-type configurations that have been well applied for fluid mixing in the PCR chips (Hashimoto et al., 2006; Münchow et al. 2005). Hashimoto et al. presented Y-shaped passive micromixer to mix the continuous-flow PCR product and ligation detection reaction (LDR) cocktail for the detection of low-abundant DNA point mutations (Hashimoto et al. 2006). Meanwhile, the passive Y-type microchannel was developed to induce the reproducible metering and merging of two or more fluid volumes (0.1–10 μL) without any active valve components or external sensors in PCR chips (Münchow et al. 2005).

Chen and Zhao (2017) designed and optimized the obstacles of a three-dimensional T-type micromixer. The mixing index of above 0.9 is achieved for a wide range of Peclet numbers. The obstacles in T-type micromixers can improve the mixing performance than the conventional T-type micromixer (Chen and Zhao 2017). Another T-type micromixer with obstacles was presented also by Rasouli et al. (2018). The curve micromixer designed to create normal advection and curved microchannels to generate Dean vortices. The mixing index used in the range of 0.48–0.89 with a pressure drop of 195.6 Pa to 10,891.6 Pa for Reynolds number = 27 and mixing index range of 0.73–0.98 with a pressure drop of 1695.9 Pa to 35,543.8 Pa for Reynolds number = 81 is achieved (Rasouli et al. 2018).

Figure 5. Schematic illustration of microfluidic mixer that simulates instant cross-contamination and sanitization scenarios (Zhang et al., 2015).

The micromixer integrated three different mixing designs including Y-junction, Dean vortex, and chaotic was presented by Zhang et al. (2015). The micromixer is used to determine precisely the reaction time and control the chlorine concentration as shown in Figure 5 (Zhang et al. 2015). Lee et al. (2009) presented an integrated microfluidic system consist of two micropumps, a pneumatic four-membrane-type micromixer, a micro coil array, and a sample purification chamber. The simultaneous detection of IgG and IgM in two different detection chambers can be done during the detection time of just 30 min. Also, the detection limit was found to be $2.1 \times 10^{-11}\text{g}$ (Lee et al. 2009).

Kastania et al., (2016) developed a passive polymeric micromixer integrated to the microfluidic chip for DNA purification. The micromixer design is zig-zag shaped PMMA microcolumn. For the DNA purification test, fluorescein (MW-332.21) which have a diffusion coefficient of $4.9 \times 10^{-10} \text{ m}^2/\text{s}$ is used. The mixing index of 0.95 is reached for 5 $\mu\text{L}/\text{min}$ per inlet and 0.88 for 10 $\mu\text{L}/\text{min}$ per inlet (Kastani et al., 2016). Kefala et al. (2015). developed a planar split and merge passive micromixer with labyrinthine microchannels. The micromixer consists of concentric rings where flow split and merges. The mixing index above 0.85 was achieved with the 11 concentric rings and a flow rate of 2.7 $\mu\text{L}/\text{min}$ (Kefala et al. 2015). Cai et al. (2019) developed a split-recombine passive micromixer integrated into the microfluidic chip for PCR application. The spit-recombine micromixer with multiple asymmetric rings has a function to mix the sample with H_2O_2 . The mixing index of 0.85 is reached at the flow rate of 0.05 mL/min with 7 asymmetric rings applied and does not improve significantly when more asymmetric rings are added (Cai et al. 2019).

To accelerate the DNA hybridization process or to expand the immunomagnetic cell capture process efficiency, Liu et al. developed micromixer based on acoustic microstreaming (Liu et al. 2004). The micromixer was integrated with pump, valve, storage for PCR application as shown in Figure 6. The PZT actuator generates the field that induced Acoustic microstreaming. The complete mixing process in the 50 μL chamber was decreased from hours to only 6s. Furthermore, acoustic microstreaming resulted in up to 5-fold hybridization reaction kinetics acceleration with significantly improved signal uniformity. Acoustic microstreaming has many advantages over most existing chamber micromixing techniques, including simple apparatus, ease of implementation, low power consumption ($\sim 2 \text{ mW}$) (Liu et al. 2004b).

Figure 6. Schematic of the fully integrated PCR chip with a thermopneumatic air micropump and three electrochemical pumps (Liu et al., 2004b).

Another micromixer based on acoustics driven to increase antibodies-antigen binding which is forms the immunoassays such as enzyme-linked immunosorbent assay ELISA is presented by Gao et al. 2015). The external sound waves in the frequency range of 125 Hz to

150 Hz was used for micromixer. The acoustic micromixer is successfully increasing the initial binding rate of over 80% (Gao et al. 2015).

The bubble-based micromixer module fabricated with a combination of low-cost rapid prototyping techniques was presented by Conde et al. (Conde et al. 2020). The individual control of multiple micromixers embedded within the same monolithic chip can be integrated with any substrate. The static and continuous flow conditions can enhance mixing capabilities. The system is capable of performing cell-free DNA extractions from small volumes of blood plasma ($\leq 500 \mu\text{L}$) with up to a ten-fold increase. The convection mix method is used to mix the species and capillarity regulation to achieve sample transport on a single platform without the pump required is presented by Kim et al. as shown in Figure 7. The mixing rate as high as a few tens of seconds per microliter is achieved even at a low fluidic temperature of $\sim 37^\circ\text{C}$ (Kim et al. 2009).

Figure 7. Schematic illustrations of single-chamber micromixing and PCR (Kim et al. 2009).

RESEARCH CHALLENGES

One of these research challenges is materials limitations. Most of the microfluidic devices are fabricated using polyurethane methacrylate which is showing elastomeric behaviors such as polydimethylsiloxane (PDMS) (Kim et al. 2009; Conde et al. 2020; Kastani et al. 2016). In the late of 1990s, the utilization of PDMS is growth to fabricate much microfluidic research because of its compatibility with the soft lithography process (Kefala et al. 2015; Cai et al. 2019). However, PDMS has many limitations and is not suitable for mass production (Chiu et al. 2017). Also, PDMS also suffers from swelling with chemicals (Lee et al. 2003). On the other hand, glass or silicon substrates are robust but require advanced fabrication processes whose cost. Interestingly, the silicon and glass are emerging as important materials for microfluidic devices with integrated electrodes, high aspect ratio channels, and able to patterned by e-beam. However, the glass materials become one of constraint when the fabrication processes required to create a deep channel in glass (Toan et al. 2016). Furthermore, the other issue is the fragility of the material.

The issues of PDMS in all microfluidic devices also should be considered. Several issues using PDMS which are as follows:

- 1) Hydrophobic small molecular absorption: Due to the PDMS has hydrophobic property from polymer network structure, the utilization of fluorescent molecules to diffuse and absorb into PDMS walls can allow some hydrophobic pharmaceutical drugs. This absorption and diffusion of small molecules can affect the accuracy and reliability of the experiments conducted in PDMS based devices (Toepke et al. 2006; Ren et al. 2010).
- 2) The leaching of uncrosslinked oligomers from PDMS: The residual uncrosslinked polymer chains by cured PDMS can freely diffuse the bulk material (Regehr et al. 2009).
- 3) The unstable surface property caused by oxygen plasma treatment: to facilitate chip bonding, oxygen plasma commonly used to convert the hydrophobic surface of PDMS to hydrophilic surfaces. Unfortunately, the hydrophobic properties return because the polymer chain can replace the hydroxyl groups by diffusing from the bulk to the surface (Eddington et al. 2006).
- 4) It works only in moderate temperatures
- 5) Surface roughness: It depends to the fabrication of the master molding process. When the roughness increase, a larger area for adsorption and air bubble production occurs.

In terms of the fabrication method, the microfluidic device is limited to quasi-3D planar formats. Several research groups have used 3D printing involving to print 3D microfluidic reactors and reagents in situ, and to print the master mold of microfluidic (Ho et al. 2015; Chan et al. 2016; Bohr et al. 2015). Both the resolution and cost of consumer-grade 3D printers have been plunging in recent years and are currently at a point where they are starting to be applied to microfluidic device fabrication. Direct printing will not only greatly accelerate device prototyping but also give scientists an easily accessible and empowering tool to express their creativity in the way that the introduction of PDMS soft lithography (Waheed et al. 2016; Zips et al. 2018; Cuarte et al. 2017).

The potential breakthroughs in the designs and development of these microfluidic elements within PCR chips are included as follows. First, inexpensive materials which are developed with the compatibility of MEMS fabrication techniques expanded should encourage the micropump, microvalves/micromixer to be integrated. Second, the concept of active “self-supplied” in the microfluidic becomes important within PCR chips where no external bulky pneumatic supply, valve connection tubing, and even power supply required. Third, the single-chip contains microvalves/micropumps/micromixers integrated will get larger to perform the high-throughput PCR amplification and subsequent analysis.

FUTURE: SMART MICROFLUIDIC PLATFORMS

The automation design of microfluidic has the potential to provide many of the above interesting issues. For example, Thakur et al. developed the programmable microfluidic platform for spatiotemporal over nanoliter droplets (Thakur et al. 2015). To control the micropump such as the number of pump cycles and rate of valve actuation, a programmable microvalves controller is used. Yu et al. presented a microfluidic chip for PCR application

that can automatically analyze the result detection within one hour (Yu et al. 2018). Meanwhile, Yehezkiel et al. designed a digital microfluidic with programmable order polymerization (Yehezkiel et al. 2015). The digital microfluidic can clone of assembled synthetic DNA by the PCR method. At present, the realization of functional digital microfluidic systems is still inception. Also, the digital microfluidic still equipped with many complex device apparatuses. However, the digital microfluidic performance will improve in a few years.

Many integrated circuit designers are rarely deal with semiconductor wafer or probe station. Therefore, the requirement for software experts that able to design and optimized the structure and then combine them with the fabrication experts and programmer experts so they can realize the smart microfluidic devices. Furthermore, the digital microfluidic will continue to have a significant potential application, especially in virus detection.

Future developments will relate also to bringing this technology into commercial devices worked on by non-specialists. Additionally, the requirement of standardization in microfluidic components is needed to be operated by unskilled end users. Commercialization of systems using microfluidic devices will become more frequent with many multinational companies investing heavily in microfluidic research. Devices for basic research will also remain very important, especially in the biological field due to researchers are trying to produce 'human-on-chips'. Future intelligent microfluidic platforms will also have a large impact on artificial intelligence and biological computations. This is ideal for applications, e.g., COVID-19 detection using the PCR method.

CONCLUSION

Much progress has been achieved in the microfluidic-based PCR system. Clear descriptions for every microfluidic device, namely micropump, microvalve, and micromixer used to develop the whole Polymerase Chain Reaction system are discussed in detail, including their advantages and disadvantages. It is concluded that much progress has been achieved in the microfluidic-based on the Polymerase Chain Reaction system. The future benefits of this review are to encourage the microfluidic involvement within the Polymerase Chain Reaction system, especially for the application of COVID-19 rapid detection.

Universitas Pendidikan Indonesia, Bandung, Indonesia

ABSTRACT

Coronavirus 2019 (COVID-19) epidemic has become an international concern and has posed challenges to psychological resilience in all areas. As one of the three pillars of higher education system in Indonesia, students and lecturers play a role in the community through community service program. In keeping with the present situation and circumstances, the community service program conducted this year related to the COVID-19 global pandemic. Universitas Pendidikan Indonesia lecturers and students invented and developed tools used to prevent the spread of COVID-19. The invented and developed tools were disinfectant gate, portable sink, Nano Cabin Healing, SP-WASH-O Dual Chamber Automatic Disinfectant, masks and hand sanitizer. The innovation and development of these tools are part of partnership among lecturers, students, and the Anti-COVID-19 Brigade Team in Universitas Pendidikan Indonesia. Besides, it is also part of community service programs conducted by students who are members of the UPI Organization Movement Unit Team (SGO-UPI). The students shared foods, masks, and hand sanitizers to the locals live around the university. All the community service programs were conducted to break the COVID-19 spread chain as well as to overcome and reduce the negative impacts caused by the pandemic primarily from the community's public health, environment, and economic condition.

INTRODUCTION

At the beginning of 2020, a new history in Indonesia and in more than 200 countries in the world started as we experience the Corona Virus Disease pandemic outbreak (WHO 2020). On 11 February, 2020, the World Health Organization (WHO) named the disease from the corona virus as "COVID-19," an acronym of "coronavirus disease 2019" (Razon 2020). The WHO has officially declared the COVID-19 condition to be a global pandemic and the whole world should pay serious attention to it. Thus, all public activities, including educational institutions with a large number of masses, must be halted to reduce the amount of COVID-19 virus transmission and spread (Paules, Marston and Fauci 2020).

COVID-19 is a disease caused by acute coronavirus (known as SARS-CoV-2) respiratory syndrome (Darnell et al. 2004; Perlman 2020). The deadly virus had infected the humankind after the consumption of some wild animals/birds which were being sold at the Chinese city of Wuhan (Anggraeni et al. 2020). Previous researches have shown that 54% of people in 194 cities in China encountered psychological impacts of the COVID-19 phenomena. Several factors can cause psychological impacts, one of which is the absence of human interaction due to lockdown and social isolation in different regions and countries around the world (WHO 2020). Women and students were the two most psychologically impacted groups (Wang et al. 2020).

In Indonesia, university students and lecturers as a part of the higher education components play three important roles in the implementation of the three pillars of Indonesian higher education system comprising education, research, and community service which is called *Tridharma Perguruan Tinggi*. These pillars motivate lecturers and students at Universitas Pendidikan Indonesia (UPI) to take an action as a part of its contribution and dedication to society and Indonesia amidst this COVID-19 pandemic. The students and lecturers collaborated to establish a range of resources that could support health workers and the community in the midst of COVID-19 pandemic.

INNOVATION AND DEVICE DEVELOPMENT

The increasingly high spread of COVID-19 in the community encourages students and lecturers to develop devices that can be used by the community particularly the UPI community. The continuation of this device making is based on the issue that emerges amid the need of the community to address the COVID-19 high spread. The developed devices include the production of disinfectant gate to prevent the current spread the COVID-19 pandemic (Figure 1). It is made from a combination of iron with 2.1 meters high and 3.2 meters wide, and works by spraying the disinfectant liquid on vehicles (Medina 2020). The spraying chemicals are hydrogen peroxide (H_2O_2) and hypochlorite sodium ($NaHOCl$).

Furthermore, the disinfectant gate and disinfectant fluid innovation were made as a collaboration between UPI lecturers and students. Also, the UPI task force team created a portable sink tool (Figure 2) to support people who are still working outside the house and around UPI area, in an attempt to support the community and prevent COVID-19 (Humas UPI 2020).

Figure 1. Disinfectant gate.

Figure 2. Portable sink.

Besides the aforementioned devices, lecturers and students also invented some other devices. Collaborating with the UPI Anti-COVID-19 Brigade Team, they created Nano Cabin Healing (Figure 3). The Nano Cabin Healing is a device used to overcome COVID-19 and other respiratory diseases, designed to improve the treatment of human immunity and the lung by means of a nano droplet injection technique. Nanoparticles are considered as the advanced materials that can perform excellently in terms of the electrical, chemical characteristics, and

so on compared to the traditional ones (Digantari and Nandiyanto 2019). Nanotechnology is the branch of science and technology conducted at the nanoscale or a billionth of a meter and it first emerged in the modern era (Nandiyanto et al. 2018) and is capable of controlling nanometer-scale substances, materials, and systems, thus generating new functions. Additionally, 1 nanometer is equal to one-billionth of a meter and is 50,000 times smaller than a human hair's size. The system was created by referring to the breathing system or human respiration.

The interaction between artificial molecular assemblies or nanodevices and biomolecules can be used in extracellular media and human cells (Boisseau and Loubaton 2011). The use of nanotechnology in cabin healing is adapted to the human respiratory system, as has been done in previous studies in Europe and America, where nanotechnology has been used in healthcare technology (Khang et al. 2010). Therefore, this Nano Cabin Healing is used to increase human immunity and respiratory treatment through the nano droplet injection technology system. The system was formed by reference to the human respiratory system. It is easy and simple to use; the patient just sits on a chair with the head goes into the cabin and the smoke will be emitted.

Figure 3. Automatic nano cabin healing.

UPI also collaborated with a ventilator expert. This collaboration aimed to create an active VENT-I device that can overcome the COVID-19 problems. Vent-I uses a Positive End-Expiratory Pressure (PEEP) ventilator for convenient operation by doctors and medical personnel.

In addition to producing nano-cabin healing, this collaboration between students and lecturers also produced Automatic Nano Sterilizer, which is a nano-technology sterilization chamber (Figure 4 in the left side).

This chamber will address the issues of virus and bacteria. The chamber works simple and swiftly because the person enters the chamber only for 10 - 20 seconds. The sprayer will

sterilize the water vapor. Since this sterilizer includes nanotechnology, the device allows the person to stay dry after sterilization. This Automatic Nano Sterilizer system could help reduce the bacteria or germs attached to the clothes or objects (Muharam 2020).

Figure 4. *Automatic Nano Sterilizer* (left) and *SP-WASHO* (right).

The innovation and productivity of students and lecturers as a community service process was carried out through the production of other devices. The team also created *Saung Paragi Wawasuh Awak diSemprot ku Halimun Otomatis* or SP-WASH-O (Figure 4 in the right side). It is a disinfectant chamber with two automatic disinfecting chambers with ultrasonic vibrator technology that can produce disinfectant steam with a size of 120-200 nanometers. The disinfection chamber has an entry point, an exit point, an enclosed area where disinfection takes place, a power supply, a solvent supply, a chemical room or mixer, an air supply, compressor (usually but not always), and a spray system (Darnell et al. 2004).

It also has optional features which include an electrical outlet for the room chamber, lighting features, audio or video options, temperature scanners, and chemical atomizers. This principle is used in the manufacture of SP-WASH-O and Automatic Nano Sterilizer tools in liquid or vapor form used for spraying disinfectants (Wickramatillake, and Kurukularatne 2020). This disinfectant chamber has been commonly used to provide medical personnel and the general public with protection and security, including many manufacturers from industries that produce and sell it.

BASIC PERSONAL PROTECTIVE EQUIPMENT

The COVID-19 phenomenon has resulted in many changes and emerges panic in the society which has caused rising prices for PPE such as masks and hand sanitizer (Hendarto 2020). This condition motivates UPI students and lecturers to help develop resources which

can be used as a community service by the local community, conducting experiments to make hand sanitizers (Figure 5 in the left side). Using hand sanitizer is also important because washing hand using soap and water is difficult to do while doing activities outside (Khosrowpour et al. 2019; Beiu et al. 2020). Being based on this, the hand sanitizers produced and distributed the local community around the university. During the COVID-19 pandemic outbreak, it also suggested that people put on masks to protect themselves as the discovery of an increase in human-to-human infection through droplets, contacts, and transmission (Pelman 2020) and people have to keep a distance and anticipate using the PPE as their personal protection especially for people with asymptomatic problem who are at high risk.

Figure 5. Hand sanitizer (left side) and face masks (right side).

Masks become one of the alternatives for protection from the COVID-19 spread as what massively happened in Wuhan, China (Cohen 2020) and the masks used have WHO standards and are adapted to the human respiratory system (Chan et al. 2020). In order to increase the awareness of using masks, the lecturers and students also produced masks (Figure 5 in the right side) and gave it to the local community along with the hand sanitizers and food. Generally, this community service is also part of the faculty to support the country in reducing and stopping the spread of the COVID-19 in the university and around its areas.

CONCLUSION

The limited conditions associated with the COVID-19 phenomenon require a great deal of creative and innovative work. Collaboration between lecturers and students in UPI established productive activities as evidence and contributions of UPI to Indonesia. Students and lecturers as a part of the elements in higher education have a role in community service activities. The community service activities carried out were collaboration between lecturers, students, UPI Anti-COVID 19 Brigade Team, and UPI Organizational Movement Unit Team (SGO-UPI) as contribution and participation for breaking the COVID-19 chain and the support to the economically affected communities around the university.

ABSTRACT

Wireless Sensor Network (WSN) application for remote monitoring and data acquisition especially during COVID-19 pandemic situation is performed. A simulation was conducted to determine the performance of WSN networks with different topologies and sizes using a Multi-hop routing. Analysis was also done in its energy usage. The WSN network in the simulation was made with Arduino-based hardware with a compatible radio transmitter module. The simulation was done in the MATLAB software environment. In the simulation, two network topologies were used, namely the Random and Grid topology and network sizes of 16 and 121 sensor nodes. It was found that the Grid topology has better performance compared to Random topology. The life time of a WSN network is not affected by the number of sensor nodes in the network, but by the amount of energy available at each sensor node.

Keywords: COVID-19, random and grid topology, wireless sensor network

INTRODUCTION

On 11 February 2020, the World Health Organization (WHO) reported the disease, namely “COVID-19,” an acronym of “coronavirus disease 2019” (Razon 2020). SARS-CoV-2 infection was first reported in Wuhan, China on 31 December, 2019 and the related literature henceforth published can help tracing the origin of the symptomatic individuals back to the early December 2019 (Anggraeni et al. 2020). During COVID-19 pandemic situation, remote monitoring and data acquisition facilitated by WSN is giving a way for application where limited human involvement and social distancing are required.

Many literatures published on the applications of wireless sensor networks (WSN) on daily life (Puccinelli and Haenggi 2005; Joshi, Nam and Kim 2003; Prathap et al. 2012; Alemdar and Ibnkahla 2007). Wireless Sensor Network (WSN) is a network of devices used to monitor the state of an environment, for example monitoring the condition of air pollution in an industrial complex, toxic gases exposure, water quality in fishponds, soil quality in agriculture, and so on. For environmental monitoring applications, WSN is characterized by the use of a large number of sensor nodes that continuously carry out measurements and send data to a number of base stations as data collectors.

Recently, the development of WSN hardware is increasingly matured supported by the development of intelligent hardware alternatives such as Xbee, Arduino and Raspberry Pi (Ferdoush and Li 2014; Kabir et al. 2014; Harikrishnan 2015; Kumbhar 2016). In this research, Arduino-based WSN nodes developed, considering its open hardware design and affordable price, although large-scale use still requires high costs. However, before the WSN hardware is developed, it is necessary to simulate the most optimal form of WSN network topology, the effect of the number of nodes, and routing schemes for transmitting data on power usage, and the efficient use of power from Arduino-based WSNs. Several studies conducted on WSN by simulation to examine the advantages of WSN (Korkalainen et al. 2009; Sobeih et al. 2006). For the application of specific hardware such as Arduino and its supporting modules, using the existing simulators is not suitable because it requires customizing the simulator software.

Thus, in this research, simulator software was made that was able to simulate the WSN in certain topologies and provide important data to researchers in analyzing WSN performance. This software made using Matlab from Mathworks, Inc. In this software, Arduino hardware is used as a reference since its ability in determining some parameters used in the simulation (Nandiyanto et al. 2018; Sukmafitri et al. 2019; Nandiyanto et al. 2019). The software created will be able to determine the most efficient topology in energy usage, fast data routing strategy, WSN network size, and maximum lifetime of a WSN network that will be implemented.

RESEARCH METHODOLOGY

Network Topology

A network with N nodes can be modelled as a curve diagram of G with N vertices so that $G = (V = \{1, \dots, N\})$, where the 2D/3D position of p of each vertex I point is expressed by the

coordinates of $p_i = (x_i, y_i, \text{ and } z_i)$. Since in this study the WSN network was simulated, the network was considered to be in a 2D plane so that the z_i coordinates above could be eliminated.

The WSN network is considered to be fully connected to each sensor node, meaning that all nodes can be reached using the multi-hop communication method. In fact, connectivity between nodes is determined by the range of the radio signal so the parameters of the range of radio signals emitted by the node must be taken into account. Equation (1) can be used to calculate the estimated radio signal range from the sensor node (Simek and Moravek 2011).

$$R = \Phi \sqrt{\frac{\log N}{N}} \quad (1)$$

The parameter Φ is the 2D plane diameter that is proportional to the number of sensor nodes N . The range of the radio signal is expressed as R . By knowing the value of R , it can be determined how much energy is required by a node to send the signal to another node.

Multi-Hop Routing

In WSN applications for monitoring environmental condition, sensor nodes are generally powered by batteries, which can be replaced if their powers are depleted. The optimal routing strategy can reduce battery's power usage, so it can extend the operational life time of the WSN network.

Routing is the process of determining the route between the starting point and destination point in terms of data transmission. Several types of protocols have been proposed to extend the network life time and to determine the route of data delivery to the network data collector, including LEACH, HEED, PEGASIS, TEEN, and APTEEN (Joshi and Priya 2012). Multi-hop communication uses less energy than single-hop over long distances between nodes. Examples of multi-hop protocols are M-LEACH (Biradar et al. 2011) and MR-LEACH (Farooq, Dogar and Shah 2012).

In this research, multi-hop routing is applied using a simpler tree-diagram-based routing. In this routing strategy, no particular sensor node is selected to be the Head of the Group as there is possibility that the Head Group node is too far away, with distance of greater than R from the surrounding nodes. In tree-diagram-based routing, data from the initial sensor node is sent to the base station through a series of other nodes that form a tree structure. Thus, each node is responsible for resending data received from the node below it. Nodes with a significant number of neighbors below it can cause energy bottleneck, where these nodes can run out of battery power in a very short time. Furthermore, Dijkstra's algorithm for determining the closest distance between nodes in a curve structure can be used to determine tree-based multi-hop route. Using grTheory toolbox for Matlab, Dijkstra's algorithm is implemented (Sergi 2009).

Energy Consumption Model

The number of messages was processed by each node during the data collection process. For 4 sensor nodes, node $n1$ starts sending data to the next node up until node $n4$. Node $n2$ receives data, checks route information, and then sends the message again to the next node. Because the sensor node uses an omnidirectional type antenna, the same message is also received again by node $n1$. However, at this time, the message received $n1$ is ignored because the recipient's identification in the message is not directed to node $n1$. Thus, node $n1$ expends energy to send an initial message of ETX and ERX energy to receive a message back from $n2$. Thus, $n1$ energy usage is:

$$E_{n1} = E_{TX} + E_{RX} \quad (2)$$

Then, node $n2$ and node $n3$ as a relay node used ERX energy to receive messages from the previous node, ETX to resend messages, and ERX to receive messages from the next node. Thus, the energy used by the relay node is:

$$E_{nr} = E_{TX} + 2E_{RX} \quad (3)$$

The last node $n4$ as the base station node is only responsible for receiving messages so that the energy used is equal to ERX.

$$E_{SB} = E_{RX} \quad (4)$$

The hardware used was an Arduino Uno R3 system with the nRF24L01 radio transceiver module. Important parameters of the radio transceiver were the electrical current consumption when sending data which was 11.30 mA, receiving data of 11.80 mA, and when the stand-by was 22 uA, the transition time from the standby state to the ready to send and receive data state that is 130 us (micro seconds), and vice versa. Another parameter is the speed of data transfer of this radio which is equal to 1 Mbps.

The length of the message which contains sensor data sent by each node is assumed based on the results obtained by Milan (Simek and Moravek 2011). In the IEEE 802.15.4 protocol, the data payload length is 30 bytes. In addition, there are also other additional messages, namely Data Request messages as long as 12 bytes, ACK messages that are used as communication controls requires 5 bytes. Total length of data transmitted between sensor nodes is 47 bytes.

Simulation Scope

There are two types of network topologies to be simulated namely grid and random topology. In a grid topology, sensor nodes are arranged at similar distance from each other to form a square. In a random topology, sensor nodes are placed randomly where the distance between nodes is made to be smaller than the value of R as shown in equation (1). For each topology, different numbers of nodes are simulated, which are 16 and 121 nodes. All nodes

are connected each other. The program determines a node that acts as the recipient of all data, called as the base station node.

Data transmission is done in a multi-hop strategy, where a sensor node sends its data to the base station node through several other nodes which serve as relay nodes. The relay node receives data and sends it again to the next relay node or directly to the base station node. It is assumed that the area where the sensor nodes installed is a rectangular area of 500 meters in length and 500 meters in width.

In the simulation, several assumptions were taken. The first assumption was that each node has energy of 1 Joule at the beginning, except the base station node which is considered to have unlimited energy so that the base station node never dies. Next assumption was that the power consumption of the Arduino base system is not taken into account as it will mask the effects of the sensor node power consumption. The last assumption was that the simulation does not considering the time for the sensor in the sleep/stand-by position.

The simulation was carried out in several rounds. One round means that all nodes, from node number 1 to number N , have sent data to the base station node. In the next round, the data transmission is repeated in similar manner. At each data transmission, the nodes use energy so that its total energy will be reduced. Nodes that do not have enough energy will be marked as a dead node and cannot participate in the next round. The simulation was stopped if the nodes located one hop before the base station node run out of energy or became a dead node, shown by the sending data to the base station node impossible.

RESULT AND ANALYSIS

The simulation was done with two types of network topologies: grid and random (as shown in Figures 1 and 2 with 16 nodes). For the random topology (Figure 1), if node 8 acts as the base station node, then nodes 1, 2, 4, 5, 6, and 13 are located 1 hop before the base station node. If all nodes die, the simulation is stopped. In the grid topology in Figure 2, if node 1 is a base station node, the node located 1 hop before is node 2, 5, and 6.

Figure 1. Random Network in Topology structure. Each node is numbered.

Figure 2. Random Network in Grid structure. Each node is numbered.

Figure 3. Number of alive nodes at the end of each round, for random topology with 16 nodes.

Figure 4. Number of alive nodes at the end of each round, for Grid topology with 16 nodes.

Figures 3, 4, 5, and 6 show the number of alive nodes at the end of each simulation round for random and grid topology with different numbers of nodes. From Figures 3 and 5, it can be seen that in the Random topology with the increasing number of sensor nodes. The dead nodes in random network happen earlier than that in grid network (see Figures 4 and 6). On the random network with 16 nodes, the first node dies at round 72, whereas at node number 121, it occurs at round 32. In the Grid topology, as shown in figures 4 and 6, for the number of nodes 16 the first node appears to die at round 143 while for the number of nodes 121 occurs at round 52. In both topology and number of nodes, all sensor nodes die at round 222.

Figure 5. Number of alive nodes at the end of each round, for Random topology with 121 nodes.

Figure 6. Number of alive nodes at the end of each round, for Grid topology with 121 nodes.

Table 1. Number of Messages Received by Base Station Node for All Network Topologies

Number of Node	Topology					
	Random			Grid		
	Number of Messages	Round	Messages/Node	Number of Messages	Round	Messages/Node
16	2630	222	164.38	3172	222	198.25
121	19826	222	163.85	20658	222	170.73

From above results, we can also analyze which topologies have better performance, whether random topologies or grid topologies. It has been mentioned before the criterion for the simulation to be considered as finished, there is no longer route for sending data from a sensor node to the base station node. This is because the node that located 1 hop before the base station node has run out of all energies. Thus, it can be counted how many data messages were successfully sent by the sensor nodes and received by the base station node. A topology with more data message received by the base station node is a better result. The number of messages received by the base station node is shown in Table 1 (Hasanah et al. 2018).

Table 1 clearly shows that the increases in number of nodes in a network allow the more data messages received by the base station node. The number of data messages received is generally greater on the Grid topology than that on the Random topology. For the Random topology, the message/node value is almost the same in the range of 164 messages/node, while for the Grid topology is in the range of 179 messages/node.

With the increasing number of sensor nodes in a WSN network, the nodes (that are concurrently serving as relay nodes) get an additional workload to relay data transmission from other nodes before going to the base station node. With more data retransmission done by relay nodes, the more energy is used so that these relay nodes run out of energy faster and eventually die earlier.

Regarding the life time of a WSN network and its relationship to the number of nodes in the network, it appears that the number of nodes in a WSN network has no effect on the life time of the sensor network. Networks with the number of nodes 16 and 121 can both make 222 rounds before the network dies. It appears that the important factor is the amount of energy possessed by each node in the network. This can be seen from Figure 2-3, where there was a sharp decrease in the number of nodes that alive in the last round due to power run out.

CONCLUSION

WSN network performance simulation has been carried out successfully with different topologies and sizes. This WSN application can be used for remote monitoring and data acquisition especially during COVID-19 pandemic situation. With the increasing number of sensor nodes in the network, the correct placement of sensor nodes is very important to prevent important relay nodes from becoming a “bottleneck” in the communication path to the base station node and shortening the life time of the WSN network. Nodes that serve as relay nodes have a greater workload than other sensor nodes so that they require more energy to perform their duty and to prevent from dying earlier than other sensor nodes. Sensor network with Grid topology performs better than that network with random topology, as distance between nodes in Grid network can be controlled.

Chapter 447

COVID-19 AND THE RISE OF TELEMEDICINE AND INTEGRATIVE MEDICINE: BENEFITS AND CHALLENGES

Wilfred W. K. Lin

Department of Computing, The Hong Kong Polytechnic University, Hong Kong

ABSTRACT

The coronavirus crisis could be the impetus the industry needs to establish telemedicine as a widespread option for access to healthcare. The Centers for Medicare and Medicaid Services have changed eligibility requirements and reimbursement limits to stem the spread of the disease, and many other payers are following suit. Payment models and regulations that have been hampering growing virtual care options for years are adapting to allow waves of patients to access their providers via telemedicine.

MAIN CONTENT

The use of telemedicine for patient evaluation is an interesting examination of telemedicine and coronavirus practice. Patients, payers, and providers who have long been skeptical of the technology see the benefits it offers, and what the new mail could be - a pandemic. In fact, virtual visits are currently being used to test patients who are symptomatic in a way that minimizes exposure. However, I expect that virus counselling in institutions will be carried out entirely remotely in the near future.

Telemedicine is likely to address some of the challenges of COVID 19, as it will allow more providers to screen and treat a larger number of patients, and patients who may be infected with the virus will no longer have to travel to a hospital or provider's practice for evaluation. Some concerns arise from the use of telemedicine, such as the potential for identifying other serious diseases, given the increased focus on symptoms and viruses.

Some commentators predict that the COVID-19 pandemic will change the way consumers seek and receive medical care, with social isolation forcing individuals to avoid doctor's offices, hospitals, and clinics. Others argue that, faced with this new reality, providers will need more financial resources and regulatory flexibility to ensure the sustainability and quality of telemedical care.

To examine the pros and cons of telemedicine, including the ways in which virtual telemedicine platforms rationalize and address the costs, accessibility, and quality of care that affect healthcare management. This includes increasing dependence on the direct administration of medicines, which leads to better access and compliance for patients.

More broadly, there could be a greater focus on prevention and wellness, which would reduce the spread of COVID 19 and increase the overall health benefits for patients in the long term. There is no doubt that the challenges identified in the health sector will also lead to an improvement in the quality of care, as well as to better access and compliance.

For pharmaceutical companies, we recommend several key success factors to weather the storm and prove to be long-term growth opportunities. Telemedicine had key strengths to improve emergency response, such as the use of telemedicine as a primary care provider and access to emergency medical services.

In infectious disease outbreaks, telemedicine can enable remote triaging and care and help diagnose the disease (see Singapore, COVID 19: 3). Telemedicine provides quickly accessible information and helps with ongoing care. There are various applications for telemedicine, such as quick access to medical records and other medical information, as demonstrated in hospitals in the United States, where physicians currently use telemedicine to care for COVID 19 patients. In addition, e-health can enable people to navigate the healthcare system more efficiently and effectively, for example through the use of social media and mobile devices.

Telemedicine, which includes this sub-category of telemedicine, has become a matter of course for healthcare providers and patients as they face the logistical and practical challenges of the COVID 19 pandemic.

A Cigna spokesman told HR Dive in an email that the company had recorded an increase in telemedical visits to its hospitals in April 2020 compared to the same period in April 2019. Given the need to shift outpatient visits to virtual, the Philadelphia-Jefferson Health hospital network has shifted from a dozen telemedicine sessions a week to 500-600 such visits a day in March, reflecting demand for a shift from face-to-face visits to virtual visits as part of the COVID-19 pandemic. A recent survey by HR Analytics, a recruitment consultancy, found that when your employer offers teleMedicines, you benefit, and there is a strong correlation between the use of these benefits and the increase in your health insurance coverage.

A recent survey by Morning Consult found that 23% of US adults are using telemedicine in the face of the COVID-19 pandemic. The biggest change to improve accessibility has been the introduction of telemedicine in the US and Canada, as well as in other countries around the world.

Employer-based health plans increasingly cover telemedicine, and New Mexico's Medicaid program allows patients with chronic conditions such as diabetes and heart disease to temporarily end public-health emergencies through telemedicine. The changes lift Medicare's restriction that only people in rural areas have access to telemedicine. Medicare now allows patients to access telemedicine from home, rather than having to go to a medical clinic. Today, the Trump administration issued a series of executive orders to help states

speed the rollout of telemedicine in the face of the COVID-19 pandemic and other health emergencies.

This release builds on the agency's efforts to provide states with the tools and guidance to support their Medicaid and CHIP beneficiaries' ability to self-care during public health emergencies.

Ensuring that patients can be cared for safely at home supports efforts to limit the spread of the virus in the community. Learn how health systems use telemedicine to address labor problems, care for at-risk groups, and ensure more efficient care.

Telemedicine providers are seeing an increase in demand as important barriers to widespread use of telemedicine disappear, including consumer awareness, acceptance by doctors and consumers (see point 4 of this story). From a lonely teenager who once struggled to connect with a broader network of friends and was tied to strict parental control, telemedicine has blossomed into the most popular child at school, becoming an indispensable tool in health care and pandemic-fighting.

California has followed in the footsteps of Massachusetts by ordering commercial health insurers to provide improved access to health services through telemedicine, including drug testing and treatment of substance-use disorders and mental health problems, and to require reimbursement rates for equivalent office visits to those of TeleHealth services. Many other payers have followed suit, and the Centers for Medicare and Medicaid Services has changed eligibility requirements and reimbursement limits to stem the spread of disease. California has abolished the requirement that all services must be provided in the recipient's home.

CMS approved Colorado's request for \$8.7 million for the use of Enhanced Federal Financial Participating (FFP), which is approved under the Affordable Care Act (ACA) for telemedical and telemedical services. On 24 April, the US Department of Health requested the CMS to review and authorize the emergency aid. Last year, CMS, the Centers for Disease Control and Prevention (CDC) and other federal agencies objected to provisions of Colorado's proposed Connected Care Pilot program, which also excluded for-profit hospitals.

Although the regulatory changes to CMS are designed to end public health emergencies, it will be difficult to move away from telemedicine overnight, even for patients who use it regularly. Because hospitals and clinics have invested time, resources, and money in building their telecommunications services, they will want to use them in the event of a pandemic.

Patients who like to use telemedicine will be confused if this option is taken away from them, especially in the event of a pandemic.

Many hospitals instruct patients with suspected coronavirus symptoms or exposure to call their doctor or call the emergency room instead of turning up for an emergency room visit. During a COVID-19 pandemic, patients and providers can use telemedicine to enable remote evaluation of patients by their providers, while respecting social distance. By using virtual visits by phone or video conference, the need for online or app questionnaires can be met, which can facilitate COVID-19 screening to determine the need for in-patient care.

From a patient's perspective, "many people will now see telemedicine," said Dr. Michael D. Schmitt, a professor of medicine at the University of Maryland, which is based in Maryland. There is a general consensus that seriously ill people should call their doctor to seek care.

But after the COVID-19 crisis forced healthcare providers to separate patients from providers, many are using remote patient monitoring platforms to care for infected and potentially contagious patients in their own homes. Booker said the coronavirus has enabled

healthcare providers to use telemedicine and mHealth tools more often as a first port of call to assess what their patients need and choose a course of action that reduces wasteful costs and improves the quality of care.

Since COVID 19 began, the healthcare industry, which is on the axis of a pandemic, has seen a decline in the number of healthcare providers willing to introduce and deploy this model of patient care. This decline can be observed because telemedicine is a relatively new technology that is not used by most healthcare institutions. It seems that the popularity of telehealth will continue to rise as long as COVID 19 still exists.

Telemedicine may represent a fundamental change in patient engagement, but can it be sustained and can the technology sustain itself in the long term?

The current iteration of express care online has been around for about six years, and many hospitals in the region have some kind of telemedicine infrastructure, said Dr. Matthew D. Miller, director of the clinic's telemedicine program. The clinic announced last year that it was working with American Well to create a joint venture with the digital healthcare company to provide broad access to telemedicine based on an existing partnership between the two. Many hospitals quickly bought webcams and other technologies, trained hundreds of providers in the technology, and in some cases expanded bandwidth and IT capacity. Some systems have had some forms of telemedicine for years; in one case, they had to reschedule thousands of patient appointments because of lack of bandwidth, according to a report by the Center for Digital Health.

The clinic is working to redesign its approach to meet the demand for patients "needs by finding creative new ways to provide care. The hospital's existing in-patient care, however, will be crucial in figuring out how to encourage patients to seek care from home. Doctors who beg the public to stay home show the pain and challenges facing hospitals and doctors.

As the country responds to an unprecedented coronavirus pandemic, the Centers for Medicare and Medicaid Services (CMS) is working to change its approach to telemedicine to ensure people's safety. The government is using a combination of federal, state, local, and private funding, as well as private-sector partnerships, to drive the adoption of telemedicine and ensure that the public can continue to receive health services.

A key innovation is telemedicine, which allows patients to use their mobile phones, tablets, and other mobile devices to connect with a healthcare team. For the duration of the pandemic, Medicare recipients can now stay at home and use telemedicine to visit a telemedical health office. I spoke with Dr. Michael O'Brien, director of the Medicare and Medicaid Services telemedicine program, to learn more about how telemedicine is implemented during COVID-19 pandemics.

The plan is to start with a pilot project and work out the kinks before they are implemented at FCN sites. Dr. Honey can take off her mask and step outside for a break to see her patients, and she can go out into the fresh air to chat with them.

You'd expect a few bumps on the road and headaches, but with a new technology like this it's definitely worth it.

The crack that opened the virtual floodgates came in mid-March, when the Centers for Medicare and Medicaid Services (CMS) expanded nationwide coverage of telemedicine services in Medicare. CMS announced that telemedicine services for health care providers using telemedicine providers during the COVID 19 outbreak will now be a one-on-one visit and can be paid for with a one-time payment of up to \$1,000 per visit, according to a CMS

press release. MDLinx told me about the benefits of telemedicine and the potential impact of this new technology on the healthcare system.

Fortunately, in the modern world, there is a solution that I love more and more: telemedicine. It is simply old-fashioned for a doctor to make a home visit and arrange an appointment for me in person in the near future. Based on the reactions of my clients, we can say with certainty that this is one of the most important new technologies in the healthcare system.

Once you have signed up for an account with your insurer or healthcare provider, you can use your smartphone or pad to make an appointment with a doctor or talk to the camera directly about your complaints.

Telehealth, defined by the California Telehealth Resource Center as an “attempt to improve the quality of healthcare for patients and their caregivers through telecommunications technology,” includes consulting with healthcare providers over the phone or via video chat. Historians of telemedicine often quote an 1879 article proposing the use of telemedicine telephone services for patients to reduce unnecessary visits to the doctor. Dr. Mai Phuong Nguyen began her work as an assistant professor of medicine at the University of California, San Francisco School of Medicine.

Integrative medicine, which combines alternative, conventional and complementary medicine, is designed to personalize care to optimize the quality of life and well-being of patients, emphasize prevention and promote healing. Every patient has individual needs, challenges, beliefs and circumstances. Integrative medicine has become one of the most popular forms of health care in the United States and around the world. In fact, it is becoming the second most common form of medical care after primary care, “said Dr. Michael J. Dolan, a professor of medicine at the University of California, San Diego School of Medicine.

In partnership with patients and physicians, integrative medicine seeks to treat the root causes of disease and promote health and well-being by treating and preventing disease. Mr Blackford said: “Integrative medicines provide doctors with additional methods to not only treat diseases but also promote healthy behaviours, help patients recover and maintain their health and take responsibility for improving their own health.

Integrative and functional medicine merge to support the innate healing properties of the patient. Integrative medicine, as defined by the Institute of Functional Medicine, tackles the underlying causes of disease by adopting a system-oriented approach to detecting and correcting imbalances in the body. One of the key messages is that different treatments work together based on the unique circumstances of each individual.

Although the Western medical approach is fundamental to treating patients, and its importance cannot be overstated, the recurring perception of many patients is that it often focuses on treating symptoms. By combining Eastern and Western philosophies, we can begin to treat patients more effectively and address the underlying lifestyle choices and emotional needs that contribute to the spread of chronic diseases in our society.

Simply put, it is not just about treating diseases, but about prevention, which ensures that we can feel as good as possible about our health and well-being even without illness. IM focuses exclusively on treating the disease itself and not on the symptoms of the disease itself.

Integrative medicine combines the advanced technologies of modern medicine with carefully selected modalities that have been proven to be safe and effective. Instead of restricting treatment to specific specialties, integrated medicine takes a holistic approach to treating, preventing and treating diseases. In an article by researchers in IM, I describe an

approach in medical practice that incorporates a broader perspective that surrounds the entire individual and actively involves those who can help achieve maximized health, healing, and well-being.

In recent years, the number of patients in the US and other parts of the world has grown exponentially, making it difficult for even the most motivated physicians to sift through the evidence and put it into practice.

In complementary and alternative medicine, CAM refers to therapies that extend conventional Western medicine. The term complementary describes treatments that can be used as a complement to conventional treatments, and the term alternative refers to less conventional treatments. Complementary medicine refers to treatments that are used in conjunction with standard treatment but are not normally taught in medical school.

In recent years, the term integrative health has been used to describe evidence-based CAM therapies to improve overall health such as acupuncture, chiropractic, massage and massage therapy.

People seeking treatment for a range of mental health problems can consider complementary and alternative treatment approaches to be helpful in carrying out treatment. The approach and thought process of inclusive practitioners may still be reductionist, but a strong emphasis has been placed on characterizing disorders as disorders, greatly expanding the toolbox for treating a variety of disorders such as depression, anxiety, and substance abuse.

Integrative medicine is a healing - oriented medicine that takes into account the body, mind and spirit of the whole person, including all aspects of lifestyle. Integrative medicines are therefore definitely holistic, but they use the toolbox of conventional medicine and the toolbox of non-conventional medicine, to which naturopathy also belongs. However, the extension of the instruments of integration policy may or may not apply to the identification of the root causes of disease. Leading advocates of integration point to the importance of holistic medicine as an alternative to traditional medicine, as well as its benefits and challenges.

Today's health problems require an integrated care model that includes a holistic approach to health care, not only in conventional medicine, but also in non-traditional medicine.

Patients in the head - Physical medicine understands the totality of the body, mind and spirit, and interventions address all aspects of a person. Mind - body medicine is a holistic approach to health care that combines traditional and non-traditional medicine and behavioral medicine. This partnership provides behavioral interventions in primary care, integrates complementary and conventional therapies, and modifies treatment paradigms for the benefit of the patient, his health, and well-being - not just the individual as a whole.

ABSTRACT

Telemedicine is rapidly growing as a healthcare model to provide accessible medical care to all. With increasing internet connectivity and interlinking of technology and medicine, there is no barrier for its expansion as a mainstream healthcare model. Despite all the advantages Telemedicine has, there are various challenges associated with it and thus it becomes increasingly important to address these challenges in an efficient and effective manner. The objective of this paper is to identify the challenges faced by doctors particular to neuroscience while practicing Tele medicine. For patients suffering from chronic neurologic disorders or movement inability, Tele medicine provides a virtual platform for patients to interact with the doctors with no travelling discomfort. According to recent studies, more than 40% of follow up consultations provided by neurologists and neurosurgeons can be done through Tele communication thus there is a huge upcoming demand for Tele neurology and Tele neuropathy in near future. This paper aims not only to collect a qualitative data from neurologists across the country to identify the challenges but also providing suggestions to overcome the barriers preceded by discussion and Conclusion.

INTRODUCTION

Tele medicine is a disruptive innovation in the field of healthcare sector that has changed the shape and structure of the healthcare system as a whole. Healthcare sector being the last to

adopt technology sees a sudden surge in the use of technologically driven care in the recent times. Tele-medicine that refers to remote diagnosis and treatment of patients by means of telecommunication was making its way through the years as a demand, but is now being sought after as a need. Though it had been introduced in India years back to serve the remotely placed population, in order to create equality in terms of healthcare, it is yet not deeply penetrated and adopted as a flourished healthcare delivery system. It existed in parts and fractions until the world hit a pandemic.

The worldwide covid outbreak increased the risk of contracting infection for patients visiting hospitals and other care centers. This pushed the old human touch valued healthcare delivery system towards a contactless interaction between a provider and a patient. Apart from the pandemic there were other factors such as traveling, costs associated with travelling, waiting time, non-availability of doctor, lack of access to specialized care etc that contributed to this disruption way before.

Telemedicine has proved to be game changer in the recent times. It not only benefits the sparsely populated people but also eases access for people living in urban and suburban areas. It reduces the risks associated with contracting diseases and infections at hospitals. For many non-critical conditions, regular consultations, follow ups and chronic diseases that can be treated over telecommunication platforms, it has proven to be extremely beneficial to the patients.

Patients suffering from locomotive disorders, Parkinson's disease and other movement disorders often fail to adhere to routine follow up care due to discomfort in traveling. Also most of the neurological disease patients are chronic in nature that can be treated over virtual platform and do not require one to one interaction. More than 70% of epilepsy cases can be treated over medication. Thus there is a large scope for neurologists and neurosurgeons to find their way of delivery care through Tele medicine.

However, nothing new comes without challenges, hence Telemedicine too did come with multiple challenges on a patient's as well as a provider's front. In this study we will dig deep into the challenges that providers face on a day to day basis while practicing telemedicine. With advances in technology, availability of mobile telemedicine platforms, Artificial intelligence, cloud computing, inexpensive data storage platforms there was though a surge in the telemedicine practice but there was a resistance to accept this innovation as well.

The information gap that exists between the provider and the patient becomes one of the biggest obstacles in delivering care at various steps of Tele-care such as patient assessment, exchange of information and patient management.

In order to fill this gap there are different frameworks for telemedicine which are Patient to Registered Medical Practitioner (RMP), Caregiver to RMP, Health worker to RMP and RMP to RMP which again is associated with a different set of challenges. With ease of access, there remains a question on the quality of care.

A sudden shift from human touch to tech touch there is a void in the patient's satisfaction level. Providers at the same time find it difficult to maintain the same quality of care over tech platforms than face to face interaction.

The purpose of this study is to identify the challenges faced by neurologists and neurosurgeons practicing Telemedicine.

METHODS

The research was carried out amongst neurologists and neurosurgeons practicing telemedicine in the current times. The study was quantitative in nature. For the purpose of this research, primary data was collected through a questionnaire on a Google platform. The questionnaire consisted of 17 closed ended questions. To ensure representative result, a total of 83 responses were recorded. All responses were analyzed in details for further discussion and results.

FINDINGS AND RESULTS

- Average age of the participants was 38.9 years.
- 92.8% of the participants had DM/M.CH as their highest qualification and 7.2% had MS/MD degree.
- 83.13% of the doctors were not practicing Telemedicine before Covid. However 18.07% of the doctors were practicing Telemedicine before Covid.
- Hospital Tele medicine was practiced by 72.28% of the doctors, 9.6% were practicing via common online platforms and 18.1 % of the doctors were practiced individually.
- Among Technical challenges, 86.7% faced network connectivity problems, 49.4% faced challenges in software application, 37.3% faced problem in data storage, 47% were not comfortable adopting new technology and 3.6 % faced other issues such as audio video mismatch.
- With patient interaction, 84.3% of the doctors faced challenges in exchanging patient information such as history of patient, 47% of doctors faced issues in patient management that is prescription and treatment, 37.3% of the doctors faced challenges in diagnosing the patient. 3.6% of the doctors faced other issues.
- 80.5% of the doctors preferred Tele medicine for Follow up consultation. 17.1% preferred Telemedicine for both follow up as well as First consultation and only 2.4% preferred it for First consultation.

RESULTS AND DISCUSSION

Average age of the doctors in our study was 38.9 years. Of the total respondents 92.8% hold DM/MCH degree and 7.2 hold MD/MS degree. Hospital Tele medicine was practiced by 72.28% of the doctors, 9.6% practiced via common online platforms and 18.1 % of the doctors practiced individually.

In our study we found that 81.3% of the doctors were not indulged in the practice of Tele consultation before Covid however they found their way in seeing patients through digital technology after Covid. Only 15.6% doctors were already practicing telemedicine and continue to practice now. Since the introduction of digital health in early 2000s, it was not the mainstream way of seeing patients however Covid has increased the use of Tele medicine.

With the fear of contracting virus, mandatory lockdown imposed by the government and increased awareness, patients have preferred the use of Tele consultation. At the same time doctors have also preferred the use of Tele consultation to sustain and provide care in these tough times.

Multiple technical challenges faced by doctors while practicing Tele medicine have been identified in the study. The major challenge impeding the doctor's way to telemedicine remains network connectivity faced by 86.7% of the respondents. As organizations, hospitals and various other startups continue to intermingle medical care, medical devices to digital environment, a strong network facility becomes crucially important for the functioning of this system. In a country like India, where telemedicine was implemented to facilitate the population in rural areas where hospitals and high class medical care remains untouched. The success of telemedicine still remains vague as a proper infrastructure required to ease the process of Tele consultation still lacks. Apart from network connectivity, the software system and the use of technology poses a big challenge to the doctors. 49.4% of the respondents faced issues with software application and 47% were not comfortable adopting new technology. With a sudden revolution in the process working and high integration of technology doctors struggle to shift from in person consultation to the use of high-end software and technology with ease due to lack of technical skills and training. Another technical challenge faced by 37.3% was data storage. With consultation and assessment of patients on virtual platform many doctors face difficulty in saving the data of patient for a longer time if lacking cloud storage. And presence of data on a cloud can be hacked posing a threat to data privacy and confidentiality. 3.6 % of the doctors faced issues such as audio video mismatch.

Lack of human touch has changed the scenario of communication between a doctor and a patient. 84.3% of the doctors faced challenges in exchanging patient information such as history of patient, explanation of diagnosis. The reason behind the same is intellectual gap between the patient and the doctor and the difficulty in communicating the same on a virtual platform. 47% of the doctors faced issues in patient management that is prescription and treatment. 37.3% of the doctors faced challenge in diagnosing the patient. Patient Management and diagnosis of the patient especially in the field where palpitation is crucial becomes difficult. This not only impedes the diagnosis and further care but also lessens the confidence of a doctor in the treatment. 3.6% of the doctors faced other interactive issues.

In our study, 81% of the doctors feel Tele medicine should be practiced for follow up consultation and not for first consultation whereas 17% have preferred its use for both types of consultation and only 2% prefer it for first consultation (Figure 1). First consultation requires a comprehensive diagnosis and examination of the patient along with detailed explanation of the diagnosis, condition and the treatment. However, for follow up, virtual consultation is preferred over in person consultation as it saves the cost of travel and time and also does not require detailed analysis of the patient.

There remains a question on the quality of care in virtual consultation when compared to in person consultation. In our study, 65.6% of the participants felt that the quality of care in Tele medicine is poor in relative to regular practice of consultation and 18.8% of the participants feel it is similar whereas only 3.1% feel the quality in digital health is better (Figure 2). Quality of the services is measured by the satisfaction gap among the patients which is a difference between patient's perception and patient's experience. Majority of the people trust the traditional human touch valued method of procedure. At the same doctors are

more confident and comfortable in the treatment after seeing and assessing the patient in-person. From a time perspective 48.8% of the doctors feel that online consultations take similar time as in-person consultation. And 29.3% feel that the time spent on each virtual consultation is more than the time spent on in-person consultation whereas only 22% feel that tele consultation saves time and is less time intensive (Figure 3). The doctor-patient interaction will more or less be similar in both telemedicine and in-person consultation however telemedicine reduces the overall time consumed in visiting and seeing a doctor by eliminating the travelling and waiting time.

Figure 1. Preference of Telemedicine for the type of consultation.

Figure 2. Quality compared to in person consultation.

Figure 3. Time spent per each consultation relative to in person consultation.

Privacy is a major concern when it comes to telemedicine. It was measured on a scale of 1 to 5 (where 1 refers to the least privacy and 5 refer to maximum privacy). It averaged on 3.318. Sensitive information of patient, consents are storage on cloud and transmitted through virtual methods poses a threat to the confidentiality of the data.

Figure 4. No of responses for comfort level and quality on a scale of 1-5.

Use of technology, sensors and presence of a third player makes the communication less secure in terms of privacy. Comfort Level while practicing Tele-medicine was measured on a similar scale of 1 - 5. The average comfort level measured on 2.87. Lack of detailed examination of the patient, lack of trust on the history provided by the patients without seeing them subsequently lack of confidence in the treatment provided makes telemedicine less comfortable for the doctors.

In the debate of whether “telemedicine is here to stay”, we found that 54.2% of the doctors in our study agree to stick to the use of online consultation even after the pandemic. 37.3% remain unsure of the use of online platform to see patients after Covid. And 8.4% of the participants refuse to the use of Tele medicine.

CONCLUSION

Despite all the advantages Telemedicine provides, there is a resistance in its acceptance especially from the provider’s perspective. The major challenge is the network connectivity on both ends of the interaction. People in rural areas yet lack a good broadband connectivity which hinders the process of Tele communication. Information asymmetry between the patient and the doctor becomes a crucial factor in explaining history, diagnosis and the treatment. With only 65.38% population of India being literate and only 2% people being well versed in English there is a huge information gap between the patient and the provider. Apart from communication challenges there are technical issues. Due to lack of technical knowledge, doctors face challenges in accepting the new software systems. The comfort level with technology is relatively low when compared to one to one interaction. Telemedicine requires a strong bandwidth connection along with heavy database infrastructure to ensure

patients and doctors experience a real time consultation. There is a lack of confidence among patients and doctors that affect the trust in Telemedicine. Majority of the participants are in the opinion that Telemedicine should be used for follow up consultation and not for first consultation. Though Telemedicine decreases the cost, saves time but there is a question on the quality of the service provided. Many doctors rate the quality of care in Tele consultation poor as compared to in person consultation.

Time spent by doctors per Tele consultation is more or similar relative to the time spent per in person consultation. With more intervention of medicine with technology and improvements in telecommunication, Telemedicine will take increased role in the healthcare system. There will be more opportunities and challenges with acceptance of technology. By addressing the various challenges effectively, technology can be exploited to a larger extent to make telemedicine stay and become more standardized as a healthcare model.

Suggestions:

- With more penetration of Tele medicine in the country, availability of high bandwidth internet connectivity becomes crucially important. However bandwidth requirement decreases with advancement in technology, for real time Tele medicine there is an extensive need of Telecom innovation. Use of Artificial Intelligence and data analytics should be enhanced to improve the service delivery.
- Technical Training should be provided to doctors before they step into practicing Tele medicine. Use of software, hardware and other technical skills should be made familiar with the providers to ease the comfort with technology.
- More User friendly Applications should be made along with provision of regional language. Agile Design thinking can be applied to make better user theories thus providing a barrier free process with higher target satisfaction.
- Incorporation of Telecommunication or Technical subjects in medicine curriculum to facilitate an effective learning process for doctors to efficient adoption of Tele medicine as a healthcare delivery model.
- Real Time Consultation should be provided than a store and forward method. This not only makes the interaction easy but a real time communication has more of a care touch that provides a higher sense of satisfaction among patients.
- Tele medicine being a technology intensive field, it demands more investments in terms of technology and innovations. There is need of support to small companies providing Tele health for more financial stability and infrastructure expansion.
- Legal and Ethical laws need to be implemented and monitored to a larger extent to ensure safety of patient's rights. Since there is a heavy database of patient and doctor, the cloud storage should be managed to ensure data privacy and confidentiality.

Chapter 449

COVID-19 OUTBREAK REPRESENTS AN OPPORTUNITY FOR THE DEVELOPMENT OF INTERNET HEALTHCARE

***Huan Wang, Lin Sun, Mei Gao, Lingxia Cao,
Weixia Liu, Menghan Gao, Guixia Wang and Chenglin Sun****

Department of Endocrinology and Metabolism,
First Hospital of Jilin University, Changchun, Jilin, China

ABSTRACT

The COVID-19 epidemic has presented a severe test for the medical systems of all countries in the world. Regardless of developed or developing countries, the traditional medical service model has been dramatically affected. The traditional face-to-face treatment model has increased doctors' risk of infection. In contrast, for patients with chronic diseases, going to the hospital for treatment raises the risk of cross-infection, which seriously affects their standard medical treatment. The Internet Healthcare's non-contact treatment model, the ultra-large crowd processing capacity of computers, responsiveness that is unrestricted by time and place, multi-channel information collection, and precise diagnosis and treatment are supported by a considerable knowledge base have unleashed their full potential in the COVID-19 epidemic. Thus, these are generally considered to be reliable medical tools that can effectively perform chronic disease management amid the epidemic. COVID-19 has left us with a huge scar. Also, human society will likely face similar natural disasters in the future. So, in the face of the COVID-19 epidemic, we medical workers need to duly think about and explore medical models that align with future social development. Internet Healthcare, as an inevitable outcome of social and technological developments, needs to inherit the advantages and essence of the traditional medical model and progress on its basis. Instead of blindly relying on new technologies, it should re-examine the future of Internet Healthcare on the foundation of a traditional model. Therefore, for Internet Healthcare, this novel coronavirus pandemic is perhaps an opportunity and a challenge.

Keywords: telemedicine, COVID-19, chronic disease management

INTRODUCTION

Internet Healthcare represents a new direction for the medical industry and has the advantages of being unrestricted by time and space. It enables communication anytime and anywhere, improves medical efficiency realizing resource-sharing among all, and offers consistent and accessible medical services, which can crack some of the hard nuts in the medical industry [1, 2]. In the context of the COVID-19 epidemic, Internet Healthcare has given full play to its positive role in preventing and controlling the epidemic, by providing the general public with online medical services without leaving home, and reducing citizens' hospital-bound medical activities. It has lowered the risk of cross-infection and protected the physical and mental health of the general public. Under these special circumstances, the number of users using Internet medical services has skyrocketed. Internet Healthcare includes various forms of healthcare service with the Internet as the carrier and technical means, such as health education, medical information inquiry, electronic health records, disease risk assessment, online disease consultation, electronic prescriptions, remote consultation, and remote treatment and rehabilitation [3]. It is conducive to resolving the contradiction between the imbalance of medical resources and people's ever-increasing demand for health care. Thus, it represents the inevitable next stage in the development of the information society and the first step in the development of an intelligent medical service model.

According to a set of data released by the Planning Department of the National Health Commission of China, during the epidemic, the number of online diagnoses and treatments in hospitals affiliated with the National Health Commission has increased by 17 times compared with the same period last year. Also, the amount of consultations on some third-party Internet service platforms has grown by more than 20 times during the same period, with prescriptions up nearly tenfold [4, 5]. After the outbreak of COVID-19, in not only China but also the United States, where the Internet medical industry originated in the early 21st century, the US government encouraged using online medical treatment instead of offline treatment. It adjusted its Internet medical care and health insurance policy accordingly [6]. The French Ministry of Health signed a decree in March 2020, allowing National Health Insurance to reimburse patients with COVID-19 symptoms and confirmed COVID-19 infection via remote video consultation and remote professional services. These remote services have had a specific effect on reducing unnecessary face-to-face medical consultations by limiting the number of people in the waiting room for triage, screening and identifying suspected patients, and enabling the follow-up of confirmed mild cases at home [7]. In Asia, South Korea, one of the first countries to develop Internet Healthcare, has been affected to a certain extent due to national medical policy restrictions. However the outbreak of the pandemic prompted it to respond to the Internet's need to provide access to healthcare services. It actively adopted various policy measures to boost Internet Healthcare as a medical solution to the pandemic [8, 9].

Internet Healthcare presents an effective solution to the current medical plight and is embracing an opportunity for its development [10, 11]. However, because of the limitations of medical policies and diverse treatment approaches among countries, the development of

intelligent Internet Healthcare has yet to explore and build advanced intelligent medical functions, such as a smart medical cloud and medical equipment informatization. During the development of intelligent Internet Healthcare, excessive attention has also been paid to hardware construction, ignoring the essence of traditional medical care, which is a typical problem in the current construction and development of intelligent medical treatment. For example, it is common to focus on hardware construction while ignoring the essence of intelligent medical care.

The COVID-19 epidemic has changed our lives, requiring more patients to experience and accept the treatment model of Internet medical services. After patients used the Internet Healthcare application during the epidemic, we found that this chronic disease management model was feasible in real life. As humans, our society is undergoing the initial steps of the fourth technological revolution, but Internet medical care remains in its infancy. So, we must take the initiative to explore the expansion potential of Internet Healthcare and work hard to solve predictable problems both currently and prospectively. Only in this way, can we effectively respond to the new challenges brought forward by Internet Healthcare.

COVID-19 OUTBREAK, AN OPPORTUNITY FOR THE DEVELOPMENT OF INTERNET HEALTHCARE

At the end of December 2019, 2019, novel coronavirus (2019-nCoV) infections and suspected pneumonia cases emerged in China, especially in Wuhan of Hubei Province, and other countries. Cities and villages in various parts of China implemented lockdown, and residents were isolated at home, as required. The sudden outbreak of the epidemic severely affected the standard diagnosis and treatment in the hospital. In the early stage of the outbreak, the treatment for the epidemic itself and the anxiety triggered by the disease has caused an influx of patients into the hospital, resulting in an insufficient supply of offline medical resources and weak response. The ensuing measures, such as the designation and renovation of fever clinics, designated hospitals, and suspension of admission, have put medical institutions into an irregular operation state. In addition, patients with chronic diseases were at high risk of infection and death during the COVID-19 epidemic. They refrained from standard medical treatment because of the social fear of cross-infection. Thus, in the context of the COVID-19 epidemic, Internet Healthcare was re-examined as a medical solution to the epidemic based on its advantages, such as non-face-to-face medical treatment, convenient consultation regardless of temporal and locational restrictions, and feasibility of traceable, and monitorable follow-ups [12-14].

Regarding the age of the clinical patients during the epidemic, most infected patients were between 40 and 60 years old, and many of them were older people with underlying diseases or obesity. Wuhan of China was the first place of the epidemic outbreak. Huang et al. also released data on the epidemiological analysis of 41 patients first diagnosed in China in *The Lancet*, among whom 32% were chronic patients with diabetes, hypertension, coronary heart disease, and others, and up to 20% were diabetics alone. In other words, diabetic patients are likely to be susceptible to this epidemic, mainly due to their chronic hyperglycemia, which itself will cause damage to blood vessels, the nervous system, and various other organs [15]. In a meta-analysis related to COVID-19, Bulut evaluated a total of

46,248 patients in eight epidemiological studies of COVID-19 and found that the most common comorbidities were hypertension, diabetes, cardiovascular disease, and respiratory diseases [16]. Another finding of this study showed that these patients with comorbidities were more likely to deteriorate into severe cases. In addition, according to Italian Weekly, the most common COVID-19 comorbidities were hypertension, diabetes, ischemic heart disease, and chronic kidney disease, each accounting for 72%, 31.5%, 27.4%, and 23.5%, respectively. It also revealed that patients without comorbidities comprised only 2.8% of deaths [18, 19]. In the face of this pandemic, patients with chronic diseases are at high risk of infection and, thus, are somewhat vulnerable. To avoid cross-infection and nosocomial infections, the number of visits by patients with chronic diseases should be reduced, and their exposure to infectious environments should be lowered. Also, it is necessary to emulate the outpatient clinic environment for them at home. Moreover, the limited distancing between people amid the COVID-19 epidemic has also triggered psychological barriers in patients with chronic diseases.

In consideration of the characteristics of the COVID-19, China's large hospitals, and Internet medical companies have rapidly rolled out online medical services [20, 21], such as (1) Online fever screening clinic: based on the existing Internet hospitals, focuses on fever, and cough clinic, emergency department, respiratory department, infection department, endocrinology department, nephrology department, cardiovascular department, geriatrics department, mental health department and general practitioners for the online screening of fever patients to provide Internet-based timely diagnosis, treatment, and consulting services. (2) Psychological intervention services: COVID-19 epidemic's prevention and control measures, such as home quarantine and social distancing between people of more than one meter, have induced psychological barriers among psychologically vulnerable groups. These have led to a surge in psychological counseling caused by the epidemic. The home-based psychological intervention service on the Internet medical platform could also provide health education and psychological intervention before medical treatment was sought. (3) Follow-up: An Internet-based medical service could collect medical information, such as vital signs, and patients' mobile device test data after outpatient visits or discharge from the hospital, so it was suitable for uninterrupted follow-up. In addition, since it also effectively reduced the risk of cross-infection because non-contact medical treatment was not restricted by time and location, it could provide comprehensive medical services for more patients to maintain their health regularly or dynamically. (4) Remote consultation service: Internet Healthcare also provided technical support for remote consultations between medical institutions. The application of 5G to back up high-definition remote consultations could keep medical images clear, seamless, and without delay so that doctors can read images freely, the technical accuracy of image reading became enhanced. High-quality expert resources could be shared with primary medical institutions, allowing for real time interaction. It has also provided technical support for the overall arrangement and command, medical treatment, and joint prevention, and control of higher-level medical institutions through the remote consultation platform between medical institutions amid the epidemic. (5) Online medical payment: Internet hospitals have connected with online medical insurance payment platforms to improve online diagnosis and treatment, follow-up examinations after chronic disease treatment, online payment, drug delivery, and other services, which effectively reduced the risk of crowd aggregation and cross-infection. (6) Application of artificial intelligence (AI): Medical assistant robots (AI) reduced the workload of nurses, cut down their contact time

with suspected and confirmed COVID-19 patients, and lowered the consumption of materials for prevention and control. Meanwhile, AI-assisted temperature measuring instruments were also used to screen the key population. The application of AI to the decision-making analysis of patient diagnosis and treatment could deliver continuous, comprehensive, individualized decisions through an overall evaluation of patients' medical information [22, 23].

The promotion of Internet medical services has not only effectively reduced the number of outpatient visits but also ensured that the demand for medical treatment is met. Through online contact between doctors and patients, the latter have gained more knowledge and methods of epidemic prevention and self-management. Also, adverse events caused by delayed treatment of chronic diseases have been avoided. Based on our research experience of Internet Healthcare, we performed it for diabetes during the COVID-19 epidemic. Our research team independently developed the u-diabetes.com system to enable doctors to make a diabetes diagnosis and prescribe treatment over the Internet, and the WeChatDiabetes mobile medicine system for patients [24-26]. With the popularity of smartphones, person-to-person communication has been separated from the Internet-based on computers, and is conducted mainly through chat tools on mobile phones. Previous studies have found that it is challenging for older patients to learn unfamiliar Apps, and they seldom use other Apps besides those to surf the Internet, communicate, and chat on smartphones, which is chiefly because most Apps are complicated to operate. However, if you allow older patients to open their commonly used chat tools, and then enter the mini-program, they will adopt a whole new attitude toward using it. This is because first, they are familiar with it, and second, they know the basic operation of the App. Although we have also developed an independent App for patients on mobile phones, we still insist on collecting information from the chat App for patient convenience. We also discovered that this was more beneficial for patients to receive information on time and not delay feedback. The reason is that if you want to know the push information on a mobile phone, you must ensure that the App is on the homepage of the phone screen. Interestingly, almost all of us will keep a chat App on the main screen of our phones. In addition, even if we accidentally erase it, we will ask others to help restore the chat App to the main screen if we cannot do it ourselves, thereby ensuring that the information is sent to the patient the first time.

During the epidemic, considering that many older patients tend to have a limited mastery of new technology, we have repeatedly conducted online video guidance and uploaded blood glucose data via blood glucose meters with a data transmission function (which can be directly connected to a smartphone via Bluetooth). Patients were required to measure blood glucose at least twice a day for 2-3 days a week. In the WeChatDiabetes mobile medicine system, subjects could check their blood sugar level, blood pressure level, and weight changes. During the epidemic, our doctors logged into the system every two weeks and adjusted drugs in time through App messages or phone calls according to the data uploaded by the subjects voluntarily, to avoid the occurrence of hyperglycemia or hypoglycemia. Meanwhile, patients were urged to adhere to blood sugar self-monitoring and strengthen diet and exercise management. Regular online medical treatment registration from patients was also accepted. Moreover, based on patients' ideal weight and nature of work, nutritionists calculated the total daily calories patients needed concerning their original living habits, determined the composition of nutrients, and formulated the recipe for three meals after converting the calories into food. Fitness trainers arranged regular aerobic and resistance

exercises for patients at least 150min a week according to different conditions such as age, sex, physical activity, and complications.

During the epidemic, we did not ask patients to go to the hospital to check glycosylated hemoglobin, but only analyzed their blood sugar control. The main purpose of patients seeking online medical treatment from February to March when the epidemic was the gravest was that patients were unable to perform online medical treatment normally because of their social fear of the sudden outbreak. They were seeking online medical treatment not to solve problems related to blood sugar control, but to consult on the novel coronavirus and how people with diabetes could prevent it. Therefore, we have produced a WeChat promotional video with the theme of “Improving Immunity and Fighting Off the epidemic.” Our Internet medical platform was based on the WeChat platform and thus had very good reach, reporting many patient clicks up to 8000. We found that patients’ top priority was to attain medical information about this serious public health emergency. So, we arranged staff to provide counseling on the platform to avoid blind and extreme behaviors of diabetics and help them enter on a normal path of self-management of diseases. In April, with the stabilized control of the epidemic in China and the gradual resumption of daily life, patients’ online medical treatment for diabetes began to increase steadily. On the contrary, the number of outpatient visits has decreased by more than 10% compared with previous years. The grim warning of diabetic patients’ susceptibility to infection and subsequent death has severely hindered their desire to seek offline, face-to-face medical treatment.

Internet Healthcare provides a safe solution during the COVID-19 outbreak and is a suitable fit for patients and the actual social situation. This epidemic also serves as a turning point in the transformation of medical service models and an opportunity for the development of Internet medical service.

THE SPACE FOR INTERNET MEDICAL DEVELOPMENT, PROFESSIONAL MEDICAL SERVICES FOR THE GENERAL PUBLIC

As a product of the times, Internet Healthcare also needs continuous improvement and expansion. The current Internet Healthcare primarily facilitates the communication of medical information between doctors and patients, and the circulation of finances and goods, which applies to all clinical departments. However, the difference in Internet Healthcare of chronic disease lies in its intelligent follow-up capabilities, such as monitoring, early warning, and clinical decision-making assistance. These advantages can be extended to many clinical departments and patients with specific diseases, and incorporate more groups, including sub-healthy groups, and the general population in need of health management.

The department of endocrinology is the primary clinical department for chronic disease management. Diabetes is currently the most suitable disease for Internet Healthcare [27]. Diabetes self-management includes medication, diet, exercise, and blood glucose monitoring. The timely sharing and analysis of blood glucose monitoring data are crucial to prevent hyperglycemia and hypoglycemia [28]. The development of glycosylated hemoglobin and diabetic complications can be predicted from the changes in a patient’s blood glucose level and routine clinical indicators, which are the most accurate reminders for patient self-management. In addition, diet, and exercise management also require monitoring data of

caloric intake and calorie used, as these two daily activities have a great impact on blood glucose. Only by combining these two influencing factors to adjust drugs can the patient's actual condition be objectively reflected [29, 30]. The prevalence of thyroid disease is increasing each year, and more than 300 million people in the world suffer from it, making it the second largest disease in the endocrine field. At present, about one in six women has hypothyroidism [31]. If the patient is pregnant, the probability of miscarriage, and fetal mortality in the third trimester significantly rises. It is very likely to lead to impaired intellectual development and growth disorders of the newborn, causing irreparable harm to the mother and child. However, it is also unrealistic for pregnant women to frequently seek medical treatment offline. Also, those with metabolic diseases need professional monitoring and treatment throughout the whole process [32]. In this aspect, Internet Healthcare has a unique advantage in the remote management of metabolic diseases during pregnancy [33]. Patients with diabetes, hypertension, and thyroid diseases are followed up through terminal monitoring equipment. In addition to the clinical nutrition department's intervention on drugs and endocrine metabolic diseases also needs to combine dietary information collection and calorie consumption monitoring with portable equipment. This combined effort could evaluate patients' daily metabolic balance and guide the nutritional follow-up of chronic diseases objectively and the diet management of metabolic diseases related to pregnancy accurately. Among patients with common kidney diseases, such as diabetic nephropathy and peritoneal dialysis, diabetic nephropathy accounts for 40% of kidney diseases. These patients key to treatment is to control their blood sugar and blood pressure. The Internet medical platform of the endocrinology department can be fully extended to the Internet-based management of nephrology patients, obtain the weight, serum potassium, and phosphorus concentration of dialysis patients, and perform accurate patient management in realtime to help improve the efficacy of dialysis [34].

In addition to the clinical departments related to endocrine diseases, coronary heart disease, hypertension, arrhythmia, and cardiovascular surgery in charge of the cardiovascular department are also suitable for Internet Healthcare [35]. Portable monitoring equipment is used in the cardiovascular field, such as a blood pressure monitor (Wireless Blood Pressure Monitor), cardiometer, and electrocardiogram [36]. The established technology has realized the portable and data transmission functions of this equipment. The monitoring data of the patient's blood pressure, heart rate, ECG, exercise volume, sleep quality, and exercise cardiac function can be automatically uploaded to the hospital server through a mobile phone in real time [37], which can provide patients with realtime and tracking monitoring services. Also, the establishment of personalized health data files based on the patient's cardiovascular signs allows doctors to understand the patient's condition and progress objectively. Respiratory diseases, including asthma, chronic obstructive pulmonary disease, sleep apnea syndrome, and other conditions, are also suitable for Internet Healthcare [38]. Portable monitoring equipment, such as a portable spirometer, can track the patient's drug use, show peak expiratory flow and lung function indicators, and use the microphone on a mobile phone to record the frequency spectrum of breath sounds. This data is then fed back to the doctor through the mobile phone. The system can interpret the data to the patient according to a comprehensive scoring method. The doctor can analyze the patient's condition and guides the patient through a standardized treatment.

Current Internet Healthcare can facilitate doctors' diagnosis and treatment activities by encouraging patients to play a more active role in assisting the clinical process in achieving

personalized, individualized diagnosis, and treatment. Outside the limitations of both time and space, Internet Healthcare can process a large amount of medical information simultaneously; it can expand its target audience from patients to sub-healthy people and healthy people who need health management [39]. Our current health management is in a passive health management model. The medical intervention is only accepted when the body is unhealthy. Medical intervention also targets a lesion by eliminating this phenomenon to relieve or cure a disease. However, active health management is a medical model that promotes the human body's adaptation by actively applying controllable stimulation to the human body. Controllable stimulation enables the enhancement of human body functions or the reversal of chronic diseases. The human body is a complex system with strong self-healing and organizing abilities. The task of medical science is to utilize controllable methods fully to activate these human body's abilities under the premise of providing the individual with the personal initiative to achieve the purpose of eliminating human diseases and enhancing the human body. This requires long-term continuous dynamic tracking, identification, and assessment of one's own state and evolutionary direction. Also, it necessitates the extensive use of various medical methods for active intervention to maintain the human body in a healthy state. Internet Healthcare meets the needs of the active health scenario. Through Internet Healthcare, the cyclical closed-loop management between hospitals, working units and families can be realized. The main scenario of active health is also in the working unit and family. Doctors are coaches for health, friends for patients, and lifestyles, such as exercise and nutrition, are tools. Internet Healthcare can take treating diseases as its purpose and can be executed based on disease prevention.

The COVID-19 epidemic is a long-term challenge that humans may encounter again in the future. This epidemic has reminded us that a healthy working style and lifestyle must be established. Everyone must change from using a passive health management model to an active health management model.

SMART HEALTHCARE IS THE CORE TECHNOLOGY FOR THE FUTURE SUCCESSFUL INTERNET HEALTHCARE

Smart healthcare is based on big clinical data, using technologies such as the Internet of Things, cloud computing, and AI as the means. It is a medical service model that is centered on patient data. The development of new information technology is profoundly changing traditional medical and health services, and big data has brought smart healthcare an unlimited development space. Smart medical solutions have potential applications in medical testing, medical image analysis, clinical decision support systems, and telemedicine [40-42].

The construction of smart healthcare, whose base is the Internet of Things technology, will be guided by intelligence with "sense, knowledge, and action" as its core. It is a smart medical platform on which medical data is more interconnected, more convenient to move, and more efficient to share. Smart healthcare solutions can continuously improve medical care accuracy through the organic operation of the data collection layer, data storage layer, business processing layer, and data application layer. "Sense" means that the family health monitoring system uses various implantable, wearable, and proximity wireless medical sensors to collect various physiological parameters of the human body. These data are

transmitted to the medical data center accurately and conveniently through network technology in real time, that is, the data collection layer [43-45]. “Knowledge” refers to using big data storage and a processing platform to model and analyze historical medical data reliably, quickly, and efficiently by applying data mining and knowledge discovery theory. It belongs to the data storage layer and business processing layer. The construction of the medical knowledge base in the data storage layer is the knowledge guarantee for smart healthcare. To achieve scientific and accurate business processing, medical experts need to make designs that simplify complex medical problems and refine simple medical problems. The data application process is the decision support for the diagnosis, treatment, and prevention of diseases, the process of fusion, screening, and analysis of multiple collected information, a design that follows the medical knowledge base and medical plan, and it should be timely and accurate in early warning and emergency response. The knowledge base includes four parts of the medical lexicon, medical term dictionary, knowledge model structure, and knowledge warehouse. The knowledge model structure forms a network structure with content related to these terms for storage and recall. The knowledge warehouse uses a powerful database as an architecture platform to assist an intelligent word processing and retrieval system. The sources of medical knowledge include medical literature (referring to archived knowledge) and the clinical experience of medical experts. For any kind of medical knowledge, the system first collects the knowledge through the acquisition engine, and then uses the knowledge model to find the corresponding solution in the knowledge base through the interpretation engine to narrow the target range gradually. Finally, the knowledge base system determines which category of medical knowledge it belongs, and stores the results in the corresponding location in the knowledge base. Auxiliary decision-making throughout the clinical process can be provided by combining simulated clinical thinking and the knowledge base. The actual process is to operate a large amount of knowledge with a neural network structure to develop medical knowledge through the following windows of “diagnosis basis,” “diagnosis of disease,” “inspection plan,” “medication plan,” “treatment plan,” “care plan,” “health plan,” and others, and generate multiple clinical decision-making channels according to the patient’s condition to provide a reference for doctors’ decision-making, so that clinical diagnosis and treatment have the nature of multi-view consultation. At the same time, it helps doctors accurately use auxiliary diagnostic methods and reduce reliance on equipment; the diagnosis, treatment, medication, and other relevant topics in the whole clinical process are included in the scope of intelligent assistance to carry out rapid, accurate, and standardized clinical diagnosis, and treatment [46, 47].

Smart healthcare can bring forward the diagnosis and treatment behavior from disease treatment to disease prevention, which can delay or prevent the occurrence and development of the disease. This advantage of smart healthcare differentiates it from traditional healthcare, and the content that needs innovation in the business processing layer. Traditional healthcare makes an accurate diagnosis through the determination of specific indicators. However, specific indicators are usually not an index for routine physical examination. The human body is an organic combination of various organs and systems. Some problems may be discovered during the routine physical examination of other organs and systems. At present, clinical examination only usually uses limited test indicator data to diagnose disease. Although many clinical test data do not significantly exceed the normal threshold of existing indicators, they may have an upward or downward trend in a certain interval. Through big data analysis and cloud computing, the logical relationship between test data and disease symptoms can be

analyzed. New disease-related markers can be revealed from these easily overlooked data. In addition, data comparison, calculation, and analysis of some conventional indicators with a variety of diseases can further discover corresponding relationships at the data level and detect new disease warning indicators through appropriate pathological verification and analysis based on big data [48, 49]. The testing of biomarkers is an important method for screening and diagnosing certain diseases. The analysis of testing big data provides new opportunities for the discovery of many disease biomarkers. Through the proteomic and metabolomic analyses of a large number of serum and urine analyses of clinical specimens of patients with chronic diseases, some abnormally expressed potential biomarkers can be found. In addition, their diagnostic efficiency is significantly higher than that of a routine examination. However, studying the change in a specific biomarker index often has only a low sensitivity or specificity. It is challenging to meet the expectations of the clinical diagnosis and prognosis of related diseases. For example, based on big data of the personalized genome, transcriptome, and proteomics, diabetes genetic marker screening adopts high-throughput, high-efficiency, and high-precision big data storage and analysis, strategies to integrate different types of data of cell phenotypes, metabolic processes, and pathogenic factors and discover significant though hidden biological markers of diabetes. Diabetes clinical index marker screening is the application of the study of existing clinical big data in the comparative analysis of diabetes risk factors, which combines traditional health data with personal data from other sources and performs a comparative analysis of health risk factors so that health-related risk factors can be selected, health monitoring and evaluation maps and diagnosis and treatment models can be made, and targeted intervention plans can be proposed [50]. Therefore, the testing of multiple markers can achieve the purpose of improving sensitivity and specificity. Integrating the biomarkers screened by various omics for data analysis will greatly improve the detection and identification of early warning signs and disease diagnoses.

“Action” is to quickly and accurately provide the analysis results of realtime data and historical data to patients through cloud services. It is necessary to form a closed-loop connection between the smart hospital system, the regional health platform, and the family health system to act effectively. The smart hospital system achieves the monitoring, tracking, chronic and infectious disease care, and the positioning and emergency deployment of medical equipment. The regional health platform can ensure a standardized diagnosis at all levels of hospitals and assist the diagnosis and treatment activities of different levels of hospitals. The family health system allows sub-healthy people to enjoy convenient, fast, and equal medical services at home through personalized health information management. The 3-sided closed-loop connection system needs to support the docking of users, such as medical institutions, collaborative consultation centers, families/individuals, enterprises, and banks through the mutual acquisition, mutual assistance, and corresponding services of cloud services and system software to realize the interaction of relevant medical information.

Based on the technological support of the data collection layer, data storage layer, business processing layer, and data application layer and the operation cases, the smart healthcare system can establish an early warning model through the storage and memorization, in-depth learning, and repeated training of massive patient clinical data, molecular data, medical images, treatment plans, and similar functions. With the aid of a large number of mathematical analysis methods, this early warning model classifies historical medical data and dynamic medical data of the patient, establishes associations and analyzes

various relationships, and extracts the characteristics and attributes of the data for comparative analysis. At the same time of making predictions, the results are fed back to the early warning model so that the model can be continuously adjusted and optimized [51].

CHALLENGES CONFRONTED BY INTERNET HEALTHCARE

Traditional healthcare strives to ensure that everyone can enjoy basic medical care and share medical resources, but it ignores the individual differences between people. With the help of new technological developments and concepts, smart healthcare can provide medical services for people according to their diseases and customize personal medical management through effective information management of medical equipment so that personalized medical management can be achieved. Also, the use of limited medical resources from disease treatment to disease prevention and healthcare can be maximized. Smart healthcare has broadened the scope of medical care and is a medical service system focusing on the full lifecycle and the whole medical process. One major feature and focus of the development of smart healthcare is the shift from disease treatment to disease prevention and healthcare. The medical process is extended to before and after the disease, focusing on health care, disease prevention, and treatment to control the disease, avoid the risk of disease, and reduce cost consumption in disease treatment and treatment costs. This approach may reduce treatment costs and relieve the patient's suffering and realize the rational use of limited medical resources.

As the online extension of the hospital's working scenario, Internet Healthcare is also a medical treatment behavior with doctors and nurses as its main body. However, the current Internet Healthcare depends too much on the design based on IT technology. Besides the hardware environment, the operation of the knowledge system and the emotional communication between people in the hospital work setting is shaped by the medical staff's study and work experience. Therefore, the design of the online working environment should be derived from the experience and designed by senior medical staff. Without sufficient medical information collection, superb logical thinking in diagnosis and treatment, and a rigorous error-correction and error-prevention system, it is impossible for doctors to achieve proper online medical behavior [52].

Sufficient medical information collection confers benefits from the data transmission capabilities of various portable devices and the development of AI recognition technology. Technologies, including the recognition and transformation of unstructured data of medical information into structured data, the recognition and digital conversion of life monitoring image information, and the integration, screening, and analysis of information from portable and home monitoring equipment, need further improvement. These improvements will enable Internet Healthcare to make full use of its own advantages to be more personalized and precise than traditional on-site diagnosis and treatment. The superb logic of diagnosis and treatment comes from the experience of senior medical workers. It cannot be replaced by clinical diagnosis and treatment manuals or diagnosis and treatment guidelines. The data and analysis processes of IBM Watson, the most representative intelligent clinical decision support system, come from guidelines, high-level literature, and experience of high-level hospitals. However, clinical practice is different from playing Go. Many factors affect the

physical condition of the human body. In addition to disease, complications, and mental conditions are contributing factors. Therefore, the diagnosis and treatment processes usually do not rely entirely on guidelines. The intelligent clinical decision support system for chronic diseases needs to be supported by sufficient personal medical information, and the integration of dynamic data. The doctor's thinking model should be strictly followed. The rigorous error-correction and error-prevention system of Internet Healthcare offers an optimal advantage. During the entire disease diagnosis and treatment process, the careful design should be established for dealing with common complicated situations, such as the identification of diagnosis and the judgment of indications and contraindications. The error-correction and error-prevention capabilities of micro-computers are a solid guarantee for the safety of Internet Healthcare.

The COVID-19 epidemic is a fight between man and nature on a global scale, which requires Internet Healthcare to expand from disease treatment to disease prevention based on its own advantages. Then, it further mandates it to maintain a healthy human body. Through the dynamic collection and comparison of health risk factors by big data technology, Internet Healthcare can select health-related risk factors and propose targeted intervention plans through an intelligent medical decision-making system to improve the comprehensive analysis capabilities of medical data and the accuracy of doctors' clinical decisions. This comprehensive medical service model of remote monitoring and intelligent diagnosis of chronic diseases is an inevitable social development trend. There is an urgent need for medical institutions to share medical diagnosis and treatment technology and patient management information on the scientific and technological service platform to realize the innovation of the chronic disease medical service model as soon as possible.

ABSTRACT

Patients infected with SARS-COV-2 are predisposed to rhythm problems primarily because of the treatment. Corrected QT interval should be calculated before using these drugs and if it is, already prolonged treatment options should be discussed. In addition, atrio-ventricular blocks may occur during the treatment, interfering with calcium channel blockers and beta-blockers, if they are already being administered. Lopinavir and ritonavir are also associated with prolonged PR and QT interval that may evolve in higher-grade atrioventricular blocks.

It is mandatory to assess whether arrhythmias in COVID-19 patients are preventable, treatable or permanent, or if they have long-term effects on the patient's cardiovascular status. Arrhythmias and cardiac arrest are more likely to be triggered by a severe, systemic form of COVID-19 and are not the sole consequence of the viral infection. In addition, electrolyte abnormalities such as hypokalemia, micro thrombi formation, cytokine storm, direct invasion of cardiomyocytes and hypoxemia may induce severe forms of arrhythmias in these patients.

Telemedicine is used to diagnose arrhythmias and permits left ventricular dysfunction assessment. It can evaluate the efficacy of antiarrhythmic therapy or the proarrhythmic side effects of patient's medication. An important application is pacemaker interrogation or automatic intracardiac defibrillator function assessment.

Telemedicine is a more permissive way to diagnose arrhythmias in these patients. However, automated interpretations are not sufficiently accurate without expert review,

^{*} Corresponding Author's Email: floria_mariana@yahoo.com.

especially in the presence of rhythm disturbances or complex abnormalities. It is limiting the time of exposure between the doctor and the patient and offers a complete overview of the disease. It is also a competitive method for triage and has screening potential.

Telemedicine can be considered to play a major part in COVID-19 patients' management, because it provides a quick and precise diagnosis that is obtained without unnecessary exposure of the medical personnel.

Keywords: COVID-19, arrhythmias, telemedicine

INTRODUCTION

Coronavirus disease 2019, known as COVID-19, is caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), resulting in a pandemic that started in the city of Wuhan late in 2019. In some cases, COVID-19 is presented with systemic manifestations that might trigger a variety of arrhythmias like atrial fibrillation, Brady arrhythmias, non-sustained ventricular tachycardia and even cardiac arrest. Critically sick patients or those admitted to intensive care units are more likely to develop these types of arrhythmias compared to other hospitalized or home based patients, primarily because of the treatment.

It is well known that drugs like hydroxychloroquine, azithromycin, lopinavir and ritonavir are involved in QT interval prolongation, so corrected QT interval (QTc) must be calculated before using these drugs and if it is already prolonged treatment options should be discussed. Atrio-ventricular blocks may also occur during the treatment making the therapy with calcium channel blockers and beta-blockers difficult, if already administered. Lopinavir and ritonavir are associated with prolonged PR interval, that may evolve into higher grade atrio-ventricular blocks.

It is mandatory to assess whether arrhythmias in COVID-19 patients are preventable, treatable or permanent, or if they have long-term effects over the patient's cardiovascular status. Arrhythmias and cardiac arrest are more likely to be triggered by a severe, systemic form of COVID-19 and are not the sole consequence of the viral infection. Electrolytes imbalance (such as hypokalemia, hypocalcemia, hypomagnesemia), microthrombi formation, cytokine storm, direct invasion of cardiomyocytes and hypoxemia may induce severe forms of arrhythmias in these patients.

Telemedicine represents a useful tool in this global context, especially when a broad range of devices like smartphones, wristwatches, patches, eye-glasses, headbands and necklaces provide a large spectrum of parameters (single or multiple-lead ECGs, heart and respiratory rate, temperature, sleep quality, blood pressure, peripheral oxygen saturation, the level of stress, apnea events, ischemia's severity and also cardio-respiratory fitness parameters).

In the case of non-COVID-19 patients with cardiovascular comorbidities who are unable to attend their scheduled appointments, telemedicine may provide complete information regarding the patient's electrophysiological status and make necessary their physical presence in our hospitals or at least limit the duration of the consult. It is an important method for triage before the patients arrive in the emergency room and facilitates a quick redistribution to other medical subspecialties.

THE SUBSTRATE OF ARRHYTHMIAS IN COVID-19 PATIENTS

In patients infected with the novel coronavirus, SARS-Cov2, the heart can be affected in many ways, the manifestation of cardiac involvement in the setting of the infection being extremely varied, as a result of direct viral damage, that is myocarditis, pericarditis or the association between them – myopericarditis, as a consequence of the homeostatic hazard caused by the respiratory infection or secondarily to the treatment given in order to manage the disorder.

In the case of primary impairment of the heart, the signs and symptoms associated with the cardiovascular system should give rise to the suspicion of SARS-Cov2 infection and, by contrast, in patients already known with COVID-19, development of the cardiac symptoms should be a warning signal, especially in those who have got already cardiovascular disease.

Arrhythmogenesis in COVID-19 Patients

Arrhythmias in patients diagnosed with COVID-19 are one of the most frequent disorders related to cardiac involvement, as studies, at this moment, indicate. In one of the very first studies addressed to COVID-19 regarding the presence of arrhythmias, in Wuhan, the epicenter of the pandemic, in a group of 168 patients, 23 had suffered arrhythmic events (16,7%), 16 of them being in intensive care unit. (Wang, et al. 2020, 1061).

Table 1. The causes of arrhythmias in COVID-19 patients

direct heart injury	dysselectrolytemia
ischemia	sympathetic nervous system over activity
hypoxia-hypoxemia	medication
systemic inflammation	previous heart damage
procoagulant status	comorbidities

The underlying arrhythmogenic process is, however, intricate. Many causes contribute to arrhythmia development but, in the end, all are related to the infection and its consequences. Table 1 sums up the main causes of arrhythmias in COVID-19 patients.

Arrhythmias Caused by Previous or De Novo Heart Injury

In this type of arrhythmias, three main causes are involved but all of them can be present at the same time (Figure 1 and Table 2).

Table 2. The mechanisms of arrhythmias in COVID-19 infection

ACUTE	CHRONIC
direct myocardial damage	proinflammatory cytokines
pericardial effusion	scars
microvascular damage	

Figure 1. The three main mechanisms of arrhythmias involving heart injury.

Direct Cardiac Injury

Coronaviruses are not cardiotropic viruses like Parvovirus B19 or Coxsackie although they use type 2 angiotensin converting enzyme (ACE2) as a receptor to invade the human organism (Zisman 2005, 323). Moreover, at this point, there is not consistent evidence that SARS-Cov2 is causing myocarditis itself. In one case report, indeed, Tavazzi and all demonstrated, for the first time, based on ultrastructural examination of endomyocardial biopsy performed on a patient with severe form of COVID-19, that the virus can be present in myocardial cells (Tavazzi, et al. 2020, 911-914). The mechanism of myocarditis in COVID-19 patients is, however, more likely to be caused by the cytokine storm, as seen in previous epidemics of SARS-Cov2 and MERS.

Apparently, myopericarditis can cause arrhythmias by intricate mechanisms, from structural damage to electric activity imbalance, some of them being prevalent in the acute phase while the others occurring in the healing or chronic phase. The presumed cytopathic effect of the virus (caused by the presence of the type 2 angiotensin converting enzyme in myocyte's membrane, that being the receptor for the virus) as seen with the established cardiotropic viruses, causes de myocyte membrane to break, thus leading to electric instability among cells. Microvascular ischemia caused by the endothelial damage associated with the cytokine high levels is also predisposing to arrhythmias, frequently at ventricular level. Cytokines, especially IL-6, cause loss of intercellular adhesion followed by cardiomyocyte necrosis and replacement with fibrous and fatty tissue, an aspect similar to that in arrhythmogenic cardiomyopathy, hence the risk of arrhythmias in COVID-19, especially the severe forms. If pericardial effusion is present it may exert a compressive effect on the heart leading to arrhythmias like bradycardia. Scars consisting of fibrous tissue give rise to arrhythmias by reentry mechanisms (Siripanthong, et al. 2020, 1464-1465).

Ischemia

Ischemia is well known for causing arrhythmias in the most varied form – from premature ventricular beats to ventricular fibrillation or conduction disturbances. In COVID-19 diagnosed patients ischemia results from the corroboration between previous atherosclerotic coronary disease and consequences attributable to pulmonary infection (Figure 2). As a result of the high inflammatory condition, fever and hypoxia generated by the pulmonary affection

and, also by the microthrombi caused by the associated procoagulant status, a mismatch between supply and demand appears. Fever causes an increase in plasma catecholamines, thus resulting in overactivity of the sympathetic nervous system, all of this causing tachycardia and contributing along with the other factors (inflammation and coagulation), to plaque vulnerability and rupture. Severe forms of pneumonia cause hypoxemia and that, in the end, contributes to myocardial ischemia and arrhythmogenesis.

Figure 2. Mechanisms of ischemia in COVID-19.

Dyselectrolytemia

Disturbances in electrolyte balance, especially hypokalemia, cause life-threatening arrhythmias. Dyselectrolytemia occurs as a result of the consequences of viral infection: dehydration caused by fever and digestive manifestations (diarrhea, vomiting) and also by involvement of the systems that are responsible with electrolyte balance (renal, digestive, pulmonary). Special attention should be given to patients receiving thiazide, thiazide-like and loop diuretics because the hypokalemia is more pronounced in these cases.

Arrhythmias Caused by Therapy Used in COVID-19

COVID-19 treatments have known continuous dynamism since the beginning of the pandemic and most of them have cardiac side effects. Also, medication used in situations like shock or cardiac arrest caused by the disease need some attention in specific cases as we will see in this chapter. The alarm signal regarding cardiac side effects of therapeutic agents refers to the QT interval prolongation and the arrhythmias that can result from this. Using some therapeutic agents (summarized in the Table 3) that are known for prolonging the QT interval, can lead to life threatening ventricular arrhythmias of which, the most feared and with the most ominous outcome, is the polymorphic ventricular tachycardia in the form of torsade des points. Also, special attention should be given to combinations of drugs that double the risk for QT prolongation: using more drugs for treating the viral infection and, also, the concomitant use of antiarrhythmic drugs that are known for interfering with the QT interval, that is, mostly, amiodarone and sotalol, raise mortality risk especially in particular cases of congenital arrhythmias like long QT syndrome.

Table 3. Drugs implicated in QT prolongation

Drugs Known for QT Interval Prolongation	
Antibiotics	chloroquine/hydroxychloroquine quinolones macrolides
Antivirals	lopinavir/ritonavir favipiravir
Immunosuppressants	tocilizumab
Antiarrhythmics	class IA – quinidine, procainamide class III – amiodarone, sotalol

Chloroquine and hydroxychloroquine are two drugs with multiple effects, used firstly for malaria treatment, then for autoimmune disorders like rheumatoid arthritis or systemic lupus erythematosus and, since 1960s, for their antiviral effects. They prolong the QT interval and widen the QRS complex. Both chloroquine and hydroxychloroquine have cardiac side effects, the only difference between them, besides the chemical one, is that hydroxychloroquine has less ocular side effects.

Their effect on QT interval occurs as a result of the interaction with some potassium channels in the cardiomyocyte's membrane, thus lowering the transmembrane potassium currents. Emerging literature has shown that lethality is higher when giving chloroquine in high doses and for short periods of time. A study conducted on 81 patients diagnosed with severe forms of COVID-19 highlights the fact that high chloroquine doses should not be given to this kind of patients, especially in cases of combinations with other drugs that can interfere with the normal sinus rhythm. The 81 patients in the study were separated in two groups and each group has received different doses: the first group consisting of 41 patients was given high doses of chloroquine (600 mg twice a day for 10 days) while the rest received low doses of the same drug (450 mg twice a day in the first day and then only 450 mg per day for a period of 4 days). Results have shown that the first group had more cases of QT interval prolongation (defined as QT > 500 ms) compared to the rest (18.9% versus 11.1%), lethality on day 13 being higher for the first group (39% versus 15%) too (Borba, et al. 2020, 1-11).

Lopinavir/Ritonavir prolong not only the QT interval but also the PR interval leading, besides ventricular arrhythmias, to atrioventricular blocks so precautions should be taken when giving betablockers or non-dihydropyridine calcium channel blockers. These drugs also exhibit side effects on hepatic metabolism of other drugs, modifying the plasma levels of some antithrombotic agents, increasing that of ticagrelor, rivaroxaban and apixaban predisposing to bleeding, but decreasing that of clopidogrel and prasugrel, thus increasing the risk of thrombotic events. They also have effects on statins, increasing the plasma levels of atorvastatin, pitavastatin and pravastatin, yet with no effect on rosuvastatin.

Macrolides (azithromycin) increases QT interval by interfering with sodium and potassium channels, leading to myocyte overload with calcium. Apparently, azithromycin is responsible for polymorphic ventricular tachycardia in the absence of QT prolongation. Although other macrolide can increase plasma levels of some drugs that can also interfere with QT interval, azithromycin has no effect in this way.

Arrhythmias Caused by Non-Cardiac Associated Diseases and Specific Medication

Among noncardiac causes of arrhythmias, we consider that it is opportune to notice three situations: that of arrhythmias caused by endocrine disorders, postoperative atrial fibrillation and that of arrhythmias in pregnant women.

Endocrine disorders can contribute to developing arrhythmias, especially atrial fibrillation, and that happens mostly because of thyroid dysfunction although disorders like pheochromocytoma or those of adrenal cortex can also lead to changes in heart rhythm. Hyperthyroidism, defined as a hyperactive thyroid, with high levels of thyroid hormones and low levels of thyroid stimulating hormone, is one of the most frequent endocrine causes of arrhythmias, leading mainly to sinus tachycardia and atrial fibrillation. Although emerging literature does not connect the SARS-Cov2 infection with the new onset of thyroid disease, we recommend that a thorough assessment of thyroid function, including the evaluation of thyroid antibodies, should be made to raise awareness of cardiac complications associated with thyroid dysfunction.

Postoperative atrial fibrillation, named by the term “new onset atrial fibrillation” is the most common arrhythmia in the postoperative period. It is not caused by the surgical process itself but by the mixture of individual factors (hypertension, atrial dilation, fibrosis related to age) with the perioperative ones (anxiety, stress of surgery, pain, hypovolemia – all of these increasing the catecholamine levels and leading to sympathetic nervous system over activity; electrolyte imbalance – mostly hypokalemia) (Yadava, Hughey and Crawford 2016, 299-308). The reported incidence for postoperative atrial fibrillation differs for different types of noncardiac surgery, being the highest in noncardiac thoracic surgery (10-30%) and having moderate percentages for colorectal surgery (5-10%). In patients requiring surgery but diagnosed with COVID-19, we consider that the risk factors multiply because of pneumonia associated hypoxia and the metabolic disturbances occurring as the virus affects more systems.

Pregnancy is a special condition because at its center there are two lives to be taken care of, that of the mother and that of the fetus. This condition might increase the risk of COVID-19 and that of more severe forms of the disease because of the pregnant women’s intolerance to hypoxia caused by the series of anatomical and physiological changes they are facing: elevated diaphragm, increasing oxygen consumption, respiratory mucosa edema caused by hormone imbalance. Also, pregnancy can be complicated by cardiac disorders and arrhythmias are not to be excluded. The most frequent arrhythmias in pregnant women are supraventricular tachyarrhythmias while ventricular ones are rather rare, mostly seen in patients with inherited arrhythmogenic disorders and probably because pregnancy usually happens in young ages while the heart does not necessarily have structural damage. Arrhythmias in pregnant women are challenging even in normal conditions, without COVID-19, due to the teratogenic effects of therapeutic agents but the presence of the infection make it more difficult to assess and treat because COVID-19 increases the risk of dysrhythmia. Therefore, we recommend, in cases of this COVID-19-pregnancy-arrhythmia triad, that a pregnancy team consisting of cardiologist, gynecologist and infection disease doctors should evaluate the patient in order to make the best decision regarding the mother-fetus wellbeing.

Types of Arrhythmias in COVID-19 Patients

A survey study conducted by the Heart Rhythm Society from March until April 2020, addressed to electrophysiology professionals, has revealed the frequency of some arrhythmia in patients diagnosed with COVID-19. Among tachyarrhythmia, atrial fibrillation was the most common (20.79% out of 683 responders). Sinus bradycardia and complete atrioventricular block were the most common bradyarrhythmias (7.69% for each out of 663 responders). Yet, this study couldn't assert if these arrhythmias were prior to infection with SARS-Cov2 or were new. As regards life threatening arrhythmias secondary to therapeutic protocol 4.1% reported torsade des points in patients receiving the combination of chloroquine/hydroxychloroquine with azithromycin (Gopinathannair, et al. 2020, 1-8).

Supraventricular Arrhythmias

The study conducted by the Heart Rhythm Society has revealed different percentages for supraventricular arrhythmias in patients diagnosed with COVID-19 (Table 4).

Table 4. Types and incidences of arrhythmias in patients diagnosed with COVID-19

atrial fibrillation	20.79%
atrial flutter	5.42%
supraventricular paroxysmal tachycardia	5.71%
sinus bradycardia	7.69%
first degree AV block	2.71%
second degree, Mobitz I AV block	1.36%
second degree, Mobitz II AV block	1.81%
complete AV block	7.69%

Sinus tachycardia. In a study conducted on 54 patients sinus tachycardia was present in every patient in critical condition (18 patients – 100%) and in 23 patients (59%) of the 39 patients with severe form of the disease (Chen, et al. 2020, 800). There are many factors that contribute to it (fever, hypoxemia, anxiety, probably viral injury of vagal nerves) but the basis consists in sympathetic nervous system overactivity.

Atrial fibrillation. As mentioned above, most studies objected that atrial fibrillation is the most frequent arrhythmia in patients diagnosed with COVID-19. Yet, treating atrial fibrillation in these patients requires some precautions. Antiviral agents should be given with caution to patients receiving class IA and III antiarrhythmic drugs because of increased risk of ventricular arrhythmias. Also, anticoagulant therapy may require dose adjustments in patients treated with lopinavir/ritonavir.

An interesting aspect has been suggested by the Danish study of Holt et al. regarding newly diagnosed atrial fibrillation. They compared the percentage of people with new diagnosis of atrial fibrillation in the first three months of 2019 with that of the same diagnosis in the same first months of the year 2020, during national lockdown, and found out that in 2020 there was a drop of 49% regarding this matter. This is not necessarily a propitious fact because the outcome of these undiagnosed patients will, most probably, be hampered by the

complications of atrial fibrillation, that is thromboembolic events, heart failure, impaired quality of life (Holt, et al. 2020, 3074).

Both sinus tachycardia and atrial fibrillation require a full assessment of cardiac status (series electrocardiograms, echocardiography), renal and liver function, thyroid hormones, electrolyte balance (mostly serum potassium, calcium and magnesium), in order to identify possible causes that can contribute to these types of arrhythmia.

Sinus bradycardia and atrioventricular blocks. These types of disturbances can be caused by hypoxia in the excito-conductive tissue because of pneumonia and microvascular disease and by inflammation secondary to cytokine storm. Pavri et al. compared the electrocardiograms of 75 patients diagnosed with COVID-19 from before and after the diagnosis to observe the PR interval adjustment with heart rate; 38 patients (50.7%) had a normal pattern: PR interval shortening with high rates. The rest (49.3% - 37 patients) experienced either a stationary PR interval length or a paradoxical prolongation, those with this abnormal pattern having a poor outcome – 11 of them died and 16 needed endotracheal intubation. By comparison, of the 38 patients with normal PR pattern, only 3 died and 8 needed to be intubated (Pavri, et al. 2020, 1434).

Ventricular Arrhythmias

As mentioned above, a series of factors contribute to ventricular arrhythmias in patients diagnosed with COVID-19 but a central role is that of long QT leading to ventricular tachycardia. In patients with long QT previous to COVID-19 treatment (either congenital or acquired), administering more than 1 drug which can further contribute to QT prolongation, increases the risk for life threatening ventricular arrhythmia. Also, using combinations of drugs can lead to increasing plasma levels of those causing QT prolongation, hence the arrhythmia risk increasing. Torsade des points is one of the most severe and feared form of ventricular tachycardia so precautions need to be taken as follows:

- calculation of QTc by Bazett formula before giving any drug that can interfere with QT duration; remember that QTc is abnormal when is >440 ms in men and >460 ms in women; Bazett formula: $QTc = \frac{QT}{\sqrt{RR}}$
- calculation of Tisdale score (Table 5) can suggest the risk of (further) developing long(er) QT
- holding back from giving drugs that can further prolongs QT interval in patients with long QT syndrome or with QTc > 500 ms;
- withholding any QT prolonging drug when the QTc has increased >500 ms or >60 ms comparing to base value of QTc;
- comparing the electrograms before and after therapy initiation;
- assessing serum potassium levels, renal and liver function;
- electrocardiographic monitoring, including telemedicine;
- treating every factor that can contribute to QT prolongation (hypokalemia, hypomagnesemia).

Table 5. Tisdale score

Risk factors	Points
age ≥ 68 years	1
female sex	1
loop diuretic	1
serum $K^+ \leq 3,5$ mEq/L	2
admission QTc ≥ 450 ms	2
acute MI	2
≥ 2 QTc prolonging drugs	3
sepsis	3
heart failure	3
1 QTc prolonging drug	3
maximum risk score	21
Low risk	≤ 6
Moderate risk	7-10
High risk	≥ 11
K^+ = potassium, MI = myocardial infarction	

Starting from the algorithm proposed by Wu et al. for initiating, supervising and withdrawing therapy with arrhythmogenic potential in patients with COVID-19 (Wu, et al. 2020, 1459), we suggest the following approach (Figure 3).

Figure 3. Algorithm proposed for follow-up of arrhythmogenic potential in patients with COVID-19.

A separate category is that of patients suffering from congenital syndromes others than long QT syndrome, which can lead to life threatening arrhythmias, those being Brugada syndrome and catecholaminergic polymorphic tachycardia.

In patients with Brugada syndrome, a congenital channelopathy, fever is known for leading to ventricular arrhythmias and sudden cardiac death and this is why it must be aggressively treated with antipyretics. Also, these patients should be placed under permanently electrocardiographic monitoring and be admitted, regardless of the form of the infective disease, in wards that have quick access to cardiac defibrillators so that medical staff could intervene promptly in cases of hemodynamically unstable arrhythmias or cardiac arrest.

As Wu et al. mention in their paper, patients with catecholaminergic polymorphic tachycardia are not at high risk if receiving the treatment for COVID-19 but they require precautions if therapy for hemodynamic support or resuscitation is needed and that because adrenaline and the other inotropic agents (noradrenaline, dopamine) cause episodes of tachycardia (Wu, et al. 2020, 1460-1461).

TELEMEDICINE IN PATIENTS WITH ARRHYTHMIAS

General Aspects of Telemedicine

Telemedicine is an umbrella term used to describe a broad variety of diagnostic, therapeutic and real-time monitoring means without involving the physical interaction between the patient and healthcare workers. Devices like smartphones or computers permit audio-video connection, while watches, wireless devices with sensors and electronic, bracelet-like devices can record and transmit physical parameters from the patients. Technology provides both advanced software and hardware components that offer qualitative recordings and artificial intelligence algorithms, to reveal only the significant information. Therefore, it is important to understand how technology works in order to see its limitations and potential sources of error (Varma N et al. 2020, 1363-1374).

A remote monitoring system is obtained when 3 major components are put together. At first, *wearable sensors* that collect specific data from the patient's skin will be placed. Then, this data will be transmitted via a *secured network* or through a special platform to a remote monitoring station where an *analytic program* based on artificial intelligence separates relevant, critical information from the redundant one and suggests possible therapeutic options. After that, physicians can let the patients know their decisions and further recommendations through a teleconferencing platform (Sana F et al. 2020, 1582-1592).

CIED's (cardiovascular implantable electronic device) interrogation offers high quality information for diagnostic and therapeutic purposes, whilst artificial intelligence is capable of sorting and organizing all the data collected from the patients and then offering diagnostic suggestions for primary care physicians or nurses. Real-time transmission is possible through secured lines and all the recorded data is sent to the patient's personal file and to the healthcare worker's computer. A new support system that facilitates clinical decisions has been implemented. CDSS (clinical decision support system) consists in a computer-based system, which processes the data received from the patients, and offers solutions to the identified issues, thus assisting the healthcare workers and optimizing the patient's

management. Early detection of life-threatening conditions, such as arrhythmias or chest pain, permits early interventions, redirecting initial diagnosis and treatment from the emergency units into primary care facilities is an option to seriously consider (Nielsen J et al. 2020, 1147–1148).

In order to understand how human sensors work, a lot of knowledge about technology and physics is required, but some basic principles are further enumerated. *Ballistocardiogram-based* technology detects repetitive movement such as heart beat or blood ejection. *Accelerometer-based* approaches are used for heartbeats and blood circulation, detecting small motions over the skin's surface, although artifacts occurrence is not a rare thing. *Photoplethysmography* signals provide information about the heart rate, but concerns about this method's accuracy have been formulated. *Phonocardiography* evaluates heart sounds, while *seismocardiography* is used for vibrations. Sensors that detect heart rate or skin's temperature can appreciate the patient's level of stress. Hospitalized patients can benefit from telemedicine through smart beds that do not need wires and limit the device-to-skin contact (Epstein AE et al. 2013, 283-352).

Telemedicine appeared as a need to reduce the burden on the medical staff and emergency care units and is not intended to replace the conventional ECG evaluation, but to give qualitative, easily accessible cardiac expertise without the disadvantage represented by distance. When telemedicine services are applied to home-based patients, they tend to be separated into two categories: those who can be monitored at home with minor therapeutic adjustments and those who must be admitted to hospital, because they demand invasive treatments or continuous surveillance. It is possible now to instantly transmit a 12-lead ECG from patient's home directly to cardiologist's computer, this system being already implemented in emergency and clinical cardiology services. One-lead ECG evaluation represents another way of monitoring the patients in places with limited resources, but an underestimation of QTc may appear when using this method. Doctors evaluate the recordings they receive and correlate them with the clinical presentation, offering a telephonic and written interpretation and possible treatment options according to the resources offered by local practices. In case of chest pain, for example, sending patients to the hospital without an ECG already performed is a stressful and time-consuming approach (Maraj I et al. 2020, 1904–1907).

In home monitored patients, it is assumed that patients alone may not place the electrodes on their chest correctly, so an initial visit to the hospital is necessary, because malposition of the electrodes is a source of errors during the recording and generates multiple artifacts. After that, the specialist's interpretation is a must, because clinical correlations and other biologic parameters may influence further therapeutic decisions. There is a chance of not being dependent on an internet connection, because the majority of devices permit an offline analysis of what they recorded.

Telemedicine, at least in a videoconference form, is highly required for emergency services, on aircraft, ships or in the case of people who live in remote locations or in isolated areas that are covered by internet connection (islands, tropical regions, mountainous region, especially during winters). Emergency services combined with telemedicine, through 4G mobile cellular systems and satellite services, permit paramedics to send the patient's data to the hospital and therefore allow doctors to analyze and prepare for the up-coming emergencies (Figure 4), especially in case of car accidents that generate multiple traumas, leading to a decrease in car accidents deaths (Sana F et al. 2020, 1582-1592).

Figure 4. Schematic representation of telemedicine services.

When an ambulance arrives at the scene, health personnel can transmit essential data (real-time images and videos, physical parameters) simultaneous with providing pre-hospital life-saving care. An increase in QALY (quality-adjusted life year) achievable through prehospital diagnosis is revealed in some studies. Studies show that younger subjects are more comfortable than older patients about sending personal data to physicians through technology, but they require less medical care services.

Telemedicine is a more permissive way to diagnose arrhythmias and permits left ventricular dysfunction assessment. It is able to evaluate the efficacy of antiarrhythmic therapy or the proarrhythmic side effects of patient's medication. However, automated interpretations are not sufficiently accurate without the expert's review, especially in the presence of rhythm disturbances or complex abnormalities. It limits the time of exposure between the doctor and the patient and offers a complete overview of the disease. It is also a competitive method for triage and has screening potential (Lieberman J, 2008, 123-126). An important application is pacemaker interrogation or automatic intracardiac defibrillator function assessment, leading to an optimal device monitoring and lowering the risk of inappropriate shocks related to these devices. Information about some forms of cardiomyopathies, myocardial ischemia or congestive heart failure can also be obtained. The importance of online platforms like Patients Like Me (<https://www.patientslikeme.com/>) cannot be neglected. This system facilitates connections between patients and increases therapeutic compliance, optimism and overall patient's education about their own disease, especially in the case of rare disorders.

A major issue that healthcare workers were confronted with was the validity of digital forms of written consent. Although this new kind of medical services is extremely permissive, verbal consent offered at the beginning of the consultation may not be enough. Patients need to be assured that their data and medical history are very well kept and a list of the departments that have access to their personal information should be provided to them every time they ask. Considering this, patients will receive some pre-evaluation documents to read and then, after they sign it, an e-mail with filled documents will be directed to physician's

computer. If they agree and sign this form of consent, healthcare providers are covered from further misunderstandings.

Although technology is evolving at a fast pace, another concern comes to light. Studies show that patients are frequently worried about their privacy, security and data ownership and do not always feel confident with their parameters being continuously recorded and transmitted to physicians and healthcare insurance companies. The recent European Union's GDPR (General Data Protection Regulation) came to limit these concerns, rigorously informing the patients and clarifying what can and cannot be done with the patient's private information, so the best interest for patients is permanently sought (Nielsen J et al. 2020, 1147–1148).

Another issue is finding a fair equivalent between the physical consultation and the telemedicine one, regarding costs and material resources usage. This pandemic found our National Healthcare services in a state where pre-defined costs were very well established for every type of consultation and procedure. This was not applied for telemedicine services too, where doctors and hospitals were challenged to adapt the way they used knowledge and resources. Financial support for hospitals is now most needed and lower income due to fewer hospitalizations and maybe cheaper telemedicine services are not something desirable.

Types of Devices Used in Telemedicine

Devices like Holter ECG's and ABPM's (ambulatory blood pressure monitoring) have a long history of use, but they have some disadvantages: their size and the likelihood to miss a rare event if it doesn't appear during the recording time. Therefore, devices that permit longer evaluation and higher quality recordings were introduced as a part of healthcare services (Table 6 and 7).

The Zio patch (iRhythm Technologies®, San Francisco, California) is a waterproof, long-term monitoring, adhesive patch, frequently applied to the left pectoral region. It generates a single lead ECG recording and has higher effectiveness in diagnosing arrhythmias, especially in the case of rare events. Palpitations, dizziness or syncope represent indications for these devices. The fact that it can be used for up to 14 days straight without recharging or changing the batteries and that it offers off-line analysis, are important advantages. An event marking button can be manually pressed by the patients when symptoms appear. At the end of the 14th day, patients send back the device to the healthcare services provider for interpretation and further recommendations.

On the other hand, NUVANT Mobile Cardiac Telemetry (MCT) (Corventis®, San Jose, California) is also a wearable monitoring patch provided with an event marking option for symptoms, but it offers wireless and real-time analysis of the rhythm disturbances.

Scanadu Scout (Scanadu®, Sunnyvale, California) is a more performant device that evaluates multiple physiological parameters such as heart and respiratory rate, blood pressure, oxygen saturation and temperature and has additional capacities for displaying, storing and even analyzing recorded data.

Smart-phone applications like Pulse-Smart (Pulse Smart®, University of Massachusetts Medical School, Worcester) and others can detect atrial fibrillation by trans-illuminating the right index fingertip using phone camera light. It ensures an important accuracy to discriminate between atrial fibrillation, sinus rhythm, premature atrial or ventricular contractions. A 12-lead ECG device called cvrPhone (Massachusetts General Hospital, Boston, Massachusetts) has the capacity of discriminating apnea events and can evaluate pro-arrhythmic or ischemic risk and even the risk for sudden cardiac death. Another kind of ECG-recording device based on mobile phones is AliveCor's Kardia Mobile (AliveCor®, Mountain View, California). Studies show that it is a better registering device than external loop recorders and can detect atrial fibrillation relatively fast. Wearable devices can also contribute to risk stratification in AF, but there are concerns regarding false positive results in

asymptomatic patients. (Varma et al. 2020, 1363-1374) ECG Check (Cardiac Designs®, Park City, Utah) uses also a smart-phone application and registers a single-lead ECG directly on the screen, instantly redirectioning it to the physician.

AF = atrial fibrillation; AZM = azithromycin; BP = blood pressure; ECG = electrocardiogram; FDA = Food & Drug Administration; HCQ = hydroxychloroquine; HR = heart rate; HRV = heart rate variability; RR = respiratory rate.

As regards oxygen's saturation monitoring, when studies compared standard pulse-oximetry to phone apps like Pulse Oximeter (DigiDoc®, Egersund, Norway), a camera-based app, or Masimo Health (Masimo®, Irvine, California), a probe-based app, results showed the non-inferiority in the first case and the superiority of probe-based devices (Varma et al. 2020, 1363-1374).

Implantable loop recorders (ILR) are small, placed under the skin devices, used for recording heart's electrical activity. These devices are used in patients with uncertain origin, rare and recurrent syncope in the absence of high-risk criteria. Another indication is in patients with high risk criteria in whom ambulatory or previous in-hospital evaluation did not identify a cause or lead to a treatment and also do not have an indication for implantable cardiac defibrillator (ICD) or pacemaker implantation. An ILR can also be considered in patients with dizziness, palpitations, frequent premature ventricular complexes or non-sustained ventricular tachycardia and in those with suspected AF or previous AF ablation.

**Table 8. ECG recording devices - benefits, performance and limitations
(modified from Sana et al. 2020, 1582-1592)**

Device's name	Benefits	Reported performance and limitations
Zio Patch	Up to 14 days utilization without battery replacement or recharge	No real-time analysis/ transmission Higher accuracy than Holter monitors;
NUVANT MCT	Real-time analysis/ transmission	Real-time data Not available to the user
Scanadu Scout	Real-time analysis Available to the user	The device is no longer used
Masimo Personal Health	Portable method to evaluate oxygen saturation Cost-effective, Noninvasive	Higher performance than standard pulse-oximetry
-	Used to perform 6-min walk test	Detects dynamic changes in cardiopulmonary function during the test
Google Glass	Higher accuracy (gyroscope vs. accelerometers)	Low mean absolute error: 1.18 beats/min for the HR 0.94 breaths/min for the RR
-	Cuff less blood pressure measurement	Precision errors: 3.3 and 8.8 mm Hg for systolic -5.6 and 7.7 mm Hg for diastolic BP
cvrPhone	Cardio and respiratory event detection	Ischemia detection within 2 min of occlusion Apnea detection within 7.9 - 1.1 s
ECG Check	Single-lead ECG Real-time analysis and transmission	Ventricular escape beat detection: sensitivity of 93.91% and predictability of 94.12%
Kardia Mobile	AF detection in less than 30 s	100% diagnostic accuracy (72.7% with external loop recorder)
Apple Watch	Lightweight Easy to operate	Patients with silent AF Sensitivity of 87% and specificity 97%
Pulse-Smart	Uses standard smartphone camera and flashlight, real-time analysis	Irregular pulse identification PAC and PVC discrimination

A novel approach is represented by in-hospital telemetry, used for high risk-patients, which also uses smart devices and may be continued even after discharge, facilitating prolonged, intensive evaluation of heart rhythm and other individual parameters such as peripheral oxygen saturation, heart rate, blood pressure and sleep quality. In-patients are frailer and may suffer acute degradation of the cardiovascular status evolving in life-threatening conditions. In their case it is very important to reduce the interactions with healthcare workers, especially if an immunosuppressed status is associated (Sana F et al. 2020, 1582-1592).

Telemedicine in Supraventricular and Ventricular Arrhythmias

Atrial fibrillation (AF) is the most frequent supraventricular arrhythmia found in patients, with a prevalence of 2% and an incidence range between 0.21 and 0.41 per 1,000 person/year, according to guidelines. AF's simplified management was proposed to cover all the concerns this disease poses and requires three main steps:

“A” Avoid Stroke with anticoagulation;

“B” Better symptom management, with a symptom-directed and patient-centered attitude regarding both the control of rate and rhythm; and

“C” The management of Cardiovascular disease and Comorbidities. Firstly, a 24h Holter ECG is recommended and if AF remains undetected although the patient continuously declares symptoms, further investigation is recommended. (Linz D et al. 2020, 1954-1955).

In case of a cryptogenic stroke, early implantation of a loop recorder that provides continuous monitoring may be the optimal decision, especially in elderly patients with cardiovascular risk factors. An important alternative is represented by trans-telephonic ECG-monitoring, external loop recorders or cardiac event recorders. Cryptogenic stroke is defined as an ischemic stroke whose etiology is still undetermined. Although its diagnosis is made by exclusion, a major cause for cryptogenic strokes is represented by undetected paroxysmal AF. Other causes are paradoxical embolism through a patent foramen oval or atherosclerotic lesions of the aortic arch, so a trans-thoracic and a transesophageal echocardiography can clarify the diagnosis and lead to a treatment (Linz D et al. 2020, 1954-1955).

Another important project is TeleCheck-AF that monitors heart rate and rhythm of patients with atrial fibrillation and offers support without the need of their presence in the hospital. It is represented by three important parts: *a structured teleconsultation*, an *app-based on-demand heart rate and rhythm monitoring infrastructure* and *comprehensive AF management*. The on-demand monitoring infrastructure consists in a photoplethysmography-based smartphone application (www.fibricheck.com) that permits a semi-continuous heart rate and rhythm evaluation of AF patients before and during the teleconsultation. The patients download the application and are instructed to evaluate their heart rhythm and rate three times daily and note correlated symptoms. All recorded data are sent via cloud, through a secured network to the physician's database for 7 days in a row and orientate the physician in indicating a treatment. Finally, the doctor re-evaluates the patient via teleconferencing and gives his recommendations (Linz D et al. 2020, 1954-1955).

Patients with unexplained syncope or during hemodialysis represent another important indication for implantable loop-recorders, because they associate a higher risk for ventricular arrhythmias and sudden cardiac death.

Telemedicine in Patients with Inherited Arrhythmia Syndromes

Brugada syndrome (BrS), Long QT syndrome (LQTS), Short QT syndrome (SQTS) and Catecholaminergic polymorphic ventricular tachycardia (CPVT) are the main types of inherited arrhythmia syndromes. Antiarrhythmic therapy and the administration of pro-arrhythmic side effect drugs are particularly challenging in these patients, so a careful monitorization is necessary. Telemedicine finds its importance in these pathologies, facilitating better healthcare and increasing survival rate in these patients (Wu CI et al. 2020, 1456-1462).

Brugada syndrome is a familial condition included in the broad spectrum of channelopathies, characterized by the type 1 ECG pattern: coved-type ST-segment elevation, J point elevation of at least 2mm and T-wave inversion in V1 and/or V2 lead. It appears due to a genetic mutation in alpha subunit of the cardiac sodium channel (SCN5A) often causing the loss-of-function in sodium channels, although other 12 mutations can be responsible for this syndrome. The absence of structural heart disease and an increased risk for ventricular fibrillation are also characteristic. Atrial fibrillation is the most frequent supraventricular

tachycardia found in these patients and comes with an important rate of inappropriate shocks when devices are used in these patients (Wu CI et al. 2020, 1456-1462).

Young patients (<45 y.o) with a family history for sudden cardiac death, often during the night is the scenario frequently presented. Type 2 and 3 of BS cannot be diagnosed with the surface ECG (although a saddle-shaped ST segment with or without elevation can be observed) and need an Ajmaline or other sodium channel blocker diagnostic test to induce the type 1 ECG aspect. Drug induced forms of BrS may also appear. Fever, especially in children, may reveal this syndrome and generate life-threatening arrhythmic events because of the sensitivity to temperature in sodium channel function. Patients with BrS should take paracetamol immediately when fever appears, those without an implantable cardiac defibrillator being at higher risk. If the temperature is over 38.5°C, emergency care should be sought, with some exceptions.

LQTS is characterized by excessively prolonged ventricular repolarization and comes with an increased risk of malignant arrhythmias such as torsade de pointes (TdP), ventricular tachycardia (VT) that may degenerate into ventricular fibrillation (VFib) and sudden cardiac death. It is an inherited pathology that is frequently revealed during childhood, so genetic testing should be performed within families when a case is discovered. Mutations in genes encoding ion channels (more often *KCNQ1*, *KCNH2* and *SCN5A*) cause electrical instability within the myocardium and an additive effect of acquired *LQTS*'s causes (such as hypokalemia, hypothermia or fever, sepsis, myocardial ischemia and a broad range of drugs) are demonstrated. Since fever and electrolytes imbalance are capable of inducing rhythm disturbances, antipyretic treatment and metabolic homeostatic status are highly recommended (Wu CI et al. 2020, 1456-1462).

Before initiating a QTc prolonging drug and after two doses of the drug an ECG assessment is mandatory and can reveal „QTc reactors”- like the patients with normal ECG's before treatment that show an intense response in QT prolongation when exposed to particular contexts. A QTc measured in 12 leads (or at lead DII and V5) and calculated through Bazett formula that exceeds 450 ms in men and 460 ms in women is considered to be prolonged. Thus, patients that undergo a QTc prolonging treatment will be separated into two groups given the risk of developing life-threatening arrhythmias: lower risk patients vs. higher risk patients. Patients considered to have a low risk for ventricular arrhythmias under QT-prolonging medication may be monitored with wearable digital devices that transmit twice daily and are capable of alerting the physician in case of an emergency (Figure 5).

Figure 5. Schematic representation of telemedicine services.

When referring to patients that are at a high-risk for QT-prolongation, long-term monitoring through telemetry and constantly evaluation of QTc interval is necessary. QTc must be evaluated at least before and after 24h, 48h and 96h from the treatment's initiation. If an increase of QTc higher than 60ms or a QTc > 500ms is detected, an important chance for ventricular arrhythmias appears, so a careful reassessment of risks over benefits in continuing the treatment is the next step to take.

Although there is a small subset of young patients with long QT-syndrome, their screening is an important matter, so when a suspicion arises, further tests should be recommended. Reversible causes for QTc prolongation will be identified and corrected rapidly. Some studies evaluated three main groups of patients while receiving hydrochloroquine alone, hydrochloroquine combined with azithromycin and compared them with placebo. Smart devices that registered a 6-lead-ECG were offered to the patients and the QTc interval was measured several times during the day. The recordings were sent to a remote QTc monitoring site, and if an increased QTc value was detected, physicians were notified. Telemedicine via smartphones turned out to be a simple, innovative and cost-efficient method to evaluate cardiovascular patients.

SQTS is an extremely rare disease caused by mutations of different types of potassium channels or in cardiac chloride-bicarbonate exchanger gene, and comes with a risk for ventricular arrhythmias.

CPVT is an inherited, autosomal dominant disorder that is frequently revealed during effort or stress, caused by some pathogenic variants in the human ryanodine receptor type 2 on a normal structural heart. Patients are often young adults or children that declare an episode of syncope. Syncope appears due to arrhythmic events like bidirectional ventricular tachycardia, polymorphic ventricular tachycardia or ventricular fibrillation generated by emotional or physical stress. Resting ECG shows a normal aspect or sinus bradycardia, but effort testing or i.v catecholamine infusion reveal the abnormalities and are diagnosed. Intensive treatment with beta-blockers is the option of choice, followed, if necessary, by flecainide administration or left sympathetic denervation. Implantable cardiac defibrillators are not usually recommended and intense emotions, effort, stress or sympathomimetic drugs need to be avoided. If an ICD is placed, there is a high risk that missed detected AF episodes will result in inappropriate shocks and pro-arrhythmic events, even death, therefore periodic, non-invasive surveillance is recommended. Telemedicine implications and necessity in these patients are demonstrated (Epstein AE et al. 2013, 283-352).

Telemedicine in Heart Failure

Heart failure exceeds 26 million cases globally, 74% of these patients having at least one additional comorbidity. Daily evaluation of weight gain does not correlate precisely with the debut of cardiac decompensation, but it is a valuable marker and in the case of an increase, over 1 kg per day, medical assistance should be sought (Gensini GF et al. 2020, 116–121).

Although telemedicine may be a very useful tool in the case of these patients, the fact that 80% of them are older than 65, slows the implementation of these techniques. Telemedicine's tools frequently require some knowledge about smart devices and computer science. In some cases, younger family members offer permanent assistance and facilitate smart device usage.

A non-invasive multidetector external device can be used to measure and immediately transmit bio-impedance parameters, physical activity duration and intensity, heart and respiratory rate, blood pressure and SpO₂. These parameters are frequently sent alongside with a predefined questionnaire in which patients declare the presence of edema, dyspnea, fatigue, dietary changes, adherence to treatment or side effects appear during the day. The information obtained from the patients is sorted by informatized programs and, after that, by qualified nurses or primary care physicians and if suggestive elements for cardiac decompensation appear, specialist physicians receive all the recorded data (Gensini GF et al. 2020, 116–21).

AF and heart failure share many common risk factors, so screening AF through frequent interrogation or remote monitoring of stored data in patients with HF can reduce the supplementary burden that is AF in HF patients. The majority of the studies show earlier intervention, a decrease in decompensating rate and an overall reduction in symptoms control and mortality from heart failure.

Telemedicine in Inherited Cardiomyopathies

Inherited cardiomyopathies like Fabry disease require a careful monitoring for life-threatening arrhythmias and sudden cardiac death. Fabry disease represents a rare, X-linked genetic anomaly of glycosphingolipid metabolism, caused by absent or severely deficient activity in lysosomal enzyme, α -galactosidase A. This disease affects the cardiac muscle by the progressive appearance of fibrosis, with an increased risk for arrhythmias, due to the electrical instability and dispersed refractory periods in the myocardium, that are rarely observed on a 24h ECG monitoring. Although a precise correlation between the location, quantity of fibrosis and the types of arrhythmias cannot be made, it seems that mid-ventricular fibrosis is linked to more cases of ventricular tachycardia (Weideman F et al. 2016, 264-274).

Weidemann et al. pinpoint clinically relevant arrhythmias in the case of Fabry disease patients: bradycardia (HR < 40 beats/minute during daytime)- for this patients an indication for pacing therapy is made; ventricular pauses (>3 seconds during daytime), also with an indication for pacing therapy; sustained or symptomatic non-sustained ventricular tachycardia, that come with an indication for ICD implantation; and finally, episodes of atrial fibrillation longer than 3 minutes who comes with an indication for anticoagulation therapy.

Considering this, permanent monitoring in Fabry disease patients becomes necessary in their multidisciplinary care algorithm, especially when they complain of palpitations, dyspnea or angina and the 24h Holter ECG does not reveal significant aspects. The place of telemedicine in this case is clear and loop-recorder devices with daily transmission to physicians are important surveillance options and should be a part of their routine clinical care. Telemedicine is to be included in primary prophylaxis of syncope and sudden cardiac death. However, the number of cases that undergo a change in clinical management is yet to be determined (Weideman F et al. 2016, 264-274).

Telemedicine in the Case of Implantable Cardiac Defibrillators and Pacemakers

Another important role of telemedicine is represented by the evaluation of ICDs, pacemakers, implantable loop recorders and CRTs (defined as CIED-cardiac implantable electronic devices), that will always be made by a fully trained physician in device implantation and follow-up. Home monitoring of implantable cardiac defibrillators with remote data access through wireless network will reduce the number of visits during a year and the annual cost of care, especially when the patient is located at longer distances. However, telemedicine cannot entirely replace clinical visits, although the information obtained is accurate and can be formatted, analyzed, easily stored and accessible. Generally, an evaluation that is made every 6 months is sufficient and safe, but there are some situations when a shorter time between presentations is required. Also, it increases the necessity of qualified staff, due to the higher amount of information that is obtained from the patients. Each manufacturer provides guidelines for appropriate device interrogation, recommended time between evaluations and potential problems associated with the device. Interrogation systems vary with the producing company. Internet based systems or radio-frequency ones have both advantages and disadvantages. Collected data is sent to central monitoring center via a smartphone and then to physicians (Figure 6), but remote reprogramming of these devices is not yet available (Varma N et al. 2016, 1363-1374).

Risk factors of ICD shock are:

1. risk factors for appropriate ICD shocks:
 - a. male sex
 - b. atrial fibrillation
 - c. elevated NT-proBNP
 - d. non-sustained ventricular tachycardia
 - e. left atrium diameter
 - f. impaired renal function
 - g. higher NYHA class
 - h. lower left ventricular ejection function
 - i. the absence of beta-blockers therapy
2. risk factors for inappropriate ICD shocks:
 - a. lower left ventricular ejection fraction
 - b. atrial fibrillation
 - c. atrial flutter
 - d. younger age

This type of evaluation prolongs ICD's life by limiting the number of inappropriate shocks that cause early depletion of the battery, but complete guidelines for remote monitoring will further be optimized. Each ICD shock promotes an increase in the mortality rate and progressive heart failure and with a number of 12-17% of patients receiving inappropriate therapy, there is a clear need for standardization and optimization in this field (Nielsen J et al. 2020, 1147–1148).

Figure 6. Schematic representation of telemedicine services through implanted devices with home monitoring function.

Acute Myocardial Infarction

A reduction of waiting time and delay in patients with acute myocardial infarction can be observed when pre-hospital telemedicine is applied and a 12 lead ECG is performed in case of a suspected acute coronary syndrome. This also generates a significant reduction in mortality because the percutaneous coronary intervention (PCI) will be performed faster, whereas emergency department is by-passed, some studies showing a decrease up to 1h or more for door to PCI time. STEMI patients who received a pre-hospital triage were associated with a lower rate of importantly depressed left ventricular ejection fraction.

CONCLUSION

In an era of continuous development of medicine knowledge and improvement of medical techniques, using telemedicine means for remote caring of patients enables health care professionals to perform a better assessment of patients' health status. Moreover, regarding the current situation generated by COVID-19, telemedicine finds its place as a helping hand for both medical personnel and patients. For cardiology matters, telemedicine occupies a leading place among diagnostic, therapeutic and monitoring means, especially in cases of arrhythmia due to all of the existing equipment and wearable devices.

Of course, like any other tool in medicine, telemedicine has its own strengths and weaknesses. We shall remember that means of telemedicine allow us to evaluate and monitor the patient whether this is happening in COVID-19 hospital wards, thus leading to limited exposure of health care professionals to the virus, or for at home patients. Because in many countries measures for limiting the patients' access to hospitals have been taken, use of

telemedicine could have improved the quality of life for those who were unable to address medical care, ensuring the patients' comfort regarding their own health and viral transmission.

Telemedicine might be a promising solution in times to come given its accessibility and it will probably lead to revolutionary changes in the health care systems.

Chapter 451

LEGAL ETHICAL DILEMMAS RELATED TO THE CARE OF COVID-19 PATIENTS THROUGH TELEMEDICINE

José Antonio García Pereáñez and David Alberto García Arango

Corporación Universitaria Americana, Barranquilla, Colombia

ABSTRACT

In this text, a reflection with a humanistic approach is made on Telemedicine in the context of the pandemic due to covid 19 and the Human Rights of patients. Situations such as the urgent demand for medical services, the eminent risk of the elderly population, the corruption of the health system in Colombia, the costs of therapeutic treatments, the existing dialectic between the promotion and prevention of health and the distance between the ethical and the legal in medical procedures; they challenge telemedicine and configure ethical dilemmas that question medical responsibility, the risk of error in teleconsultation diagnoses and decision-making. In all this situation, Communication for Health, which mediates between the state of opinion and the rule of law, has a special validity. This writing presents the analysis of a case of COVID 19 in an elderly patient, treated in the city of Medellín, in which a serious impact on their Human Rights is demonstrated in the expression of ethical dilemmas, which the health authorities could not resolve, leaving the patient's relatives in the midst of uncertainty and skepticism, in the face of government measures to address the pandemic.

Keywords: ethical dilemmas, human rights, COVID-19, telemedicine, communication for health

INTRODUCTION

For the purposes of developing the topics in this text, it is important to highlight the importance of the medical act and its relationship with telemedicine in the context of the covid-19 pandemic. Thus, the medical act includes all treatment, examination, or intervention of the patient by the doctor, for diagnostic, prophylactic or therapeutic purposes, in order to

regain their health (Perales Cabrera, 2001). Now, according to Law 1419 of 2010 of the Congress of the Republic of Colombia, telemedicine is defined with these terms: “It is the provision of distance health services in the components of promotion, prevention, diagnosis, treatment and rehabilitation, for Health professionals who use information and communication technologies, which allow them to exchange data with the purpose of facilitating access and opportunity in the provision of services to the population with limited supply, access to services or both in their geographic area.”

From the outset, two positions can be established: one, that the medical act is disfigured, as it is mediated by communication and information technologies, since it loses its humanistic, face-to-face, and synchronous categorization. Another, that the medical act is updated, reduces the costs of treatments and travel, making care effective and fast. Both positions on telemedicine are impacted by the presence of covid 19, which since March 15, 2020 has unfailingly marked the social life of the country.

According to the World Health Organization WHO, COVID 19 is the most recently discovered infectious disease caused by the coronavirus. Both this new virus and the disease it causes were unknown before the outbreak broke out in Wuhan, China, in December 2019. Currently, COVID 19 is a pandemic that affects many countries around the world.

At the beginning of March 2020, the Ministry of Health and Social Protection of Colombia announced the imminent arrival of the coronavirus, the first case was confirmed on March 6 and for the 15th of the same month the President of the Republic scheduled restrictions and confinements. The Communication for Health was in the hands of the state, opinion, and accusations of the government representatives. First, that the incipient biosecurity protocols were not properly applied at international airports, that the media misrepresented the information to their liking and that local governments did not know how to measure up to the gravity of what was happening. During this, citizenship in suspense, between skepticism and recklessness. After several months of prolonged quarantines, the collapse of the economy and the reinvention of management for many sectors of Colombian public life, the outlook is bleak. The number of deaths due to the pandemic, the lack of infrastructure for the management of patients and the insufficient resources for their care, configured some ethical dilemmas that this text intends to analyze: The ethical allocation of medical resources and the medical-medical relationship, patient in telemedicine as communicative competence for the medical act (Ratzan D, 1994).

ETHICAL ALLOCATION OF MEDICAL RESOURCES

In medical procedures during the COVID-19 pandemic, altruistic situations appear of those who give up their place and opportunities in resources, so that other young family members, also infected, can access treatments more quickly. This could be considered an ethical and moral problem, but the question reverses as follows: who should be served with the highest priority?

The state of opinion in Colombia was impacted since January 2020 with the informative presence of the coronavirus, capturing the attention of the country's news and information agents. Growing numbers of infected, dead, emerging economies and deterioration of social life, has achieved a worldwide impact of great repercussions and without any precedent.

Likewise, the already damaged health system collapsed with the number of infected and the Communication for Health was distorted in its commendable and philanthropic ideals, leaving in question the duty of medical practice and its deontological nature. The structure of society was disrupted.

This time of confinement and extensive quarantines has also questioned medical responsibility in relation to the covid 19 pandemic. Worthy and philanthropic institutions such as the World Health Organization WHO have been questioned for the handling of information in relation to the infection. Multiple clinical presentations of the virus and the constant threat of death for the most vulnerable have unfailingly constructed a scenario that oscillates between disbelief and citizen indiscipline (Ratzan D, 1994).

The ethical allocation of medical resources to face the covid 19 pandemic is part of the public health emergency declared by the National Government, but the named resources have not been equitably distributed among citizens. The hardest hit are the emerging sectors of the population, which are also the most incredulous and undisciplined in this crisis. However, the health infrastructure in Colombia consolidated the need to rationalize resources, equipment, and medical interventions. Therefore the incessant death of the elderly is not part of the dilemma of distribution of medical resources in the pandemic. It is naturalized and justified, insofar as they are the most vulnerable and the resources must be helping the youngest, for the productive life of society (Ratzan, Payne, & Bishop, 1996).

Medical decision-making is also part of this itinerary and indicates a course of ethical implications in this emergency, which has caused difficult episodes. The duty of medical practice has been questioned, while other sectors have cataloged it as heroic. Not without first mentioning that a rather significant number of health workers have been infected and others have died.

Difficult ethical decisions of medical and paramedical personnel, pressured in the midst of the crisis, with evident conditions of physical and emotional exhaustion, have been prevailing and mandatory, and this can compromise the deliberative process of a decision. This affects the fair allocation of resources in the customary altruistic and philanthropic vision of medical practice. However, the opportunities for access to health are questioned, which requires that the damage caused by the pandemic be minimal and that medical action be transparent and equitable.

THE DOCTOR-PATIENT RELATIONSHIP IN TELEMEDICINE AS A COMMUNICATIVE COMPETENCE FOR THE MEDICAL ACT

The practice of telemedicine has achieved over time the implementation of different computer tools, which have shown significant advances in the progress of “distance medicine,” applying expert tools in telematics, which have shown dizzying advances in consultation virtual, in the promotion and prevention of health (Vergeles Blanca, 2001).

According to the World Health Organization, telemedicine is “the provision of health care services, in which distance is a critical factor, by professionals who use information and communication technologies in order to exchange data to make diagnoses, advocate treatments and prevent diseases and accidents, as well as for the permanent training of health

care professionals and in research and evaluation activities, in order to improve the health of people and the communities in which they live" (IOM, 2007).

At present, the development of new technologies has had a great impact on all social, cultural and economic spheres of human life; One of them is medicine, since telemedicine or distance medicine has been implemented in the Colombian territory for two decades, which can bring significant advantages, however, the doctor-patient relationship can be affected as communicative competence in the act doctor.

Communicative competence in the medical act greatly strengthens the processes that forge the doctor-patient relationship, therefore, when this circle is suppressed, said relationship is directly affected. The importance of the bond that is created between the doctor and the patient lies in achieving a more comprehensive care, in which the spheres of the patient's life are positively influenced by medical care (Cuesta, Ugarte, & Menéndez, 2008).

Telemedicine provides greater agility when faced with solving problems, since technology greatly favors the reception of consultations, reading of exams and delivery of results, however, the implementation of this modality has brought deterioration as its main disadvantage of the close bond that is created between the doctor and the patient. Likewise, medical care through this means becomes something very elementary, leaving aside the other spheres in which a patient operates, making comprehensive care falter.

The medical *lex artis* can be compromised in multiple scenarios, the most common being in the precarious state of the health system, because in the absence of infrastructure and resources, the medical act and the doctor-patient communication are fragmented; Similarly, when in medical education there was not an adequate development of communication skills, it is possible that the doctor-patient relationship is dehumanized, it is not comprehensive and it is possible that there is an ineffective communication, having as a consequence the provision of a poor service in both situations.

Strengthening the doctor-patient relationship as a communicative competence for the medical act is of great importance so that comprehensive care is carried out in the best way, but on the other hand, in telemedicine that relationship can be violated, by preventing direct contact with the patient; However, this distance interaction that provides medical knowledge through cyberspace has allowed increasing accessibility to health services, breaking down geographic barriers.

Telemedicine establishes a model of care that today brings countless advantages in terms of care that requires agility and speed, due to the fact that technological advances are increasingly globalized, allowing greater coverage, however, communication skills in the medical profession must be preserved, since comprehensive care is a characteristic that the medical act should never lack.

A "CASE" IN THE CONTEXT OF HUMAN RIGHTS

The case study is theoretically referenced by Robert Stake (1999). It is very pertinent in ethical-legal studies and its object is made up of people. For this, the judgment derived from observation and interaction with various components related to the subject and the relationships that are structured in the case is very important. Among its characteristics is that it is an empathic, non-interventionist method. Here is the case for this study:

“Home care physician at the service of an EPS, attends the provision of services at home. Relatives request care of an adult patient over 88 years of age, who according to his relatives had an episode of nausea and vomiting with blood. Patient with a history of chronic obstructive pulmonary disease. HBP and hypothyroidism. Relatives deny respiratory symptoms. Therefore, the doctor attends the service, when arriving at the home to the simple inspection of the patient, the doctor shows respiratory difficulty, coughing spells, and significant deterioration of the general condition. Therefore, the doctor stops the assessment and proceeds to protect herself by wearing a suit for suspected covid given the current context of the patient and the ongoing pandemic. Additionally, he requests the support of a colleague to transfer the patient to the Intermediate Care Unit with adequate isolation conditions. The relatives get angry and lash out at the doctor for using the suits and, in her judgment, labeling the patient as covid, since they do not believe in the pandemic. The doctor had to make use of support from the community police line 123, since the family members verbally and physically attacked the doctor.”

The case in question is an open omission of information and a deterioration of the communicative relationship in the medical act. Hiding patient information during this pandemic becomes a clear violation of Human Rights. In his treatise on old age, “De senectute,” Marco Tulio Cicero says in a very brief sentence that “If we are not going to be immortal, it is desirable, at least, that man cease to exist in due time. Well, nature has a limit for life, as for all other things.” Also throughout the beautiful text on old age, which airs a strong stoic resignation, makes it clear that it is natural for man to turn off in his bed as the afternoon dies when the sun sets, because it is against nature to shorten life “before its time” as well as to extend it beyond what is “due” “by pouring oil like a nightlight” (Cicero, 2001).

The Colombian State is obliged to protect the lives of the elderly in the midst of the coronavirus pandemic, but this function is fully adhered to with respect for human dignity, personal autonomy, the free development of personality and the prohibition of cruel treatment and inhumane, about the inalienable rights of the person, protected by the Political Constitution of Colombia. The foregoing acquires a capital importance when these rights are invoked by a citizen who suffers from an irreversible state of health (Article 8 ACHR., 2002).

Lack of care for the elderly in the covid 19 pandemic discourages medical research, changes public awareness, violates historically accepted codes of medical ethics. The life of the weakest is in the hands of the strongest. With this, the sense of justice, reciprocity and trust in society is lost. A social and democratic collective cannot oversee the organized murder of citizens. Allowing the elderly to die during the pandemic endangers the lives of the vulnerable, corrupts medical practice, and puts at risk the family institution and generational commitment to maintaining human dignity and the equality of citizens (Garcia, 2017).

CONCLUSION

Police reports during the coronavirus pandemic assure that cases of domestic violence increased. The home became a place of fear and abuse, especially for the elderly. The situation worsens considerably in cases of isolation such as quarantines imposed during the pandemic.

During this humanitarian crisis, many elderly people have been abandoned and the bodies of many of them have been found without any mourners. This is unacceptable during a Social State of Law in justice and equity.

Immigrants and internally displaced persons are more exposed to the risk of covid 19, due to its restrictions on access to health care and decent housing. They are highly discriminated against. This crisis has unleashed xenophobia, hatred and exclusion.

COVID 19 patients treated by telemedicine access the consultation virtually, mediated their relationship with the doctor by a computer, connected to the internet in cyberspace. This allows you to know clinical information, manage documentation, make controls, communicate with doctors, use prescribed applications, observe protocols, among others. This reduces travel expenses and shortens geographic distances. Likewise, it offers the possibility of diagnosing experts located in different parts of the world, sending exams quickly and managing a wealth of medical information.

Telemedicine appears as a new contemporary paradigm in the medical vision, with little-studied models, in its expertise and benefit. The error in virtual medical practice is not conceived and there are no guarantees to hold the doctor responsible for an alleged harm to the patient. To a large extent, the practice of telemedicine is not supported by clinical protocols that can guarantee the medical practice of the “Lex Artis” (García & Others, 2019).

ABSTRACT

COVID-19 is a pandemic caused by the coronavirus, Severe Acute Respiratory Syndrome Coronavirus (SARS CoV-2), that affects the entire world, which can result in death, especially in the elderly and people with underlying disease (hypertension, diabetes mellitus, coroner artery disease). The number of patients and deaths continues to increase rapidly in the world. Today, the most important source of infection is sick people. Contagiousness in the asymptomatic and presymptomatic period is the most important problem in preventing the pandemic. The most important route of transmission is the droplets. Aerosols can be transmitted by aerosol- generating procedures in health-care. Fomites that spread to the immediate environment of sick people play a role in transmission through contact. There is insufficient data on other transmission routes. In the first period, COVID-19, which spread as a travel disease, spread to all societies in closed environments (home, meeting, public transportation, ceremonies, prisons, long-term care units...) where many people are together. Local outbreaks occur, especially in hospitals and health centers. There are many uncertainties in the pathophysiology of Covid-19. Studies at different stages of the disease and with different methodologies are published and this provides conflicting data. Lymphopenia, cytokine storm, ferritin elevation, and D-dimer elevation were found to be associated with poor prognosis. Acute respiratory distress syndrome (ARDS) and sepsis are the most important causes of mortality. In this section, a perspective for the future is presented by addressing the issues in the light of the available data.

Keywords: COVID-19, epidemiology, pathogenesis

INTRODUCTION

Coronaviruses; enveloped single-stranded, positive-sense RNA viruses. The coronavirus has a large genome of approximately 30 000 bases and an RNA polymerase activity with “proofreading” activity to correct mutations. This family is found in many mammals, especially cats, dogs, pigs, and bats, and includes important human pathogens. Viruses that adapt to new hosts with genetic recombination and variations in different hosts become important pathogens for humans when they gain the ability to be transmitted and spread from person to person. These viruses, which can settle in the respiratory and digestive systems in many mammals, were first identified as the agents with upper respiratory tract infection (HCoV-NL63, HCoV229E, HCoV-OC43, HCoVHKU1). With the clinic of Severe Acute Respiratory Syndrome Coronavirus (SARS) in 2003 and Middle East Respiratory Syndrome (MERS) in 2012, it was observed that it could cause diseases and epidemics with high mortality in humans with pneumonia. SARS-CoV-2 is an agent with long spike structures (9-12 nanometers) in dimensions of 60-120 nanometers. Bats were found as the reservoir of this virus, and although pangolin as an intermediate host was identified as the most likely source, this issue has not been fully clarified. A new coronavirus was identified as the cause of a series of pneumonia cases at the end of 2019 in Wuhan, a city in China’s Hubei province. This infection, which spread rapidly, resulted in an epidemic throughout China and then spread to other countries in the world, this epidemic was declared by WHO as a Public Health Emergency of International Importance (PHEIC). In February 2020, the World Health Organization took the name Covid-19 disease, which means coronavirus disease 19, and the virus that causes COVID-19 was named SARS-CoV-2. WHO declared COVID-19 as a pandemic on March 11, 2020. On September 25, 2020, a total of 32.110.656 detected cases and 980.031 COVID-19 deaths were recorded worldwide, and the numbers continue to increase [1].

EPIDEMIOLOGY

The global epidemiology of COVID-19 in the first phase of the pandemic was evaluated as a cross-sectional analysis using web-based surveillance [2]. In the web-based surveillance study, almost two-thirds of the COVID-19 cases first reported were those with travel links to China, Italy, or Iran. In the first period of the outbreak sixty-five studies were evaluated and most of these have been reported from China. It has been stated that most of these are due to family contacts. The major types of cluster infections were families, gatherings, religious organizations, transportation, community transmission, conferences, shopping malls, respectively [3]. Although there were many household contagion clusters among the early cases, the numbers in these clusters were low (2-22 cases) clusters in occupational or community settings tended to be larger (gathering 112, shopping mall 40, religion 53 cases was found to be affected) and physical distance was a possible risk to slow the progression of SARS-CoV-2 was supportive of its role [4]. A total of 161 studies (n = 17 648) provided data for the mode of transmission. The most common mode of transmission was travel-related (58.1%, 95% CI: 51.1-64.8), followed by close contacts (43.1%, 95% CI: 37.2-49.2), and finally community spread (27.4%, 95% CI: 18.4-38.7) [5]. At present, general findings show

that test strategies, socioeconomic differences, and reporting systems of countries affect the spread in society.

In children, it is stated that the number of cases detected is less, the disease has a milder course, and asymptomatic cases are more common in this situation. In a systemic review and meta-analysis, it is stated that approximately 4% of patients with a diagnosis of COVID-19 are symptomatic, having underlying diseases play a role in this course [6].

Severe or critical illness has been reported among 2.5% to 5% of pediatric cases, and more recently, 4% of cases were reported as severe or critical, and pre-existing medical conditions have been suggested as a risk factor for severe disease and ICU admission in children and adolescents [7]. Several countries affected by the COVID-19 pandemic reported cases of children who were hospitalized in intensive care units due to a rare pediatric inflammatory multisystem syndrome (PIMS) or multisystem inflammatory syndrome in children (MIS-C) [8], characterized by a systemic disease involving persistent *fever, inflammation* and organ dysfunction following exposure to SARS-CoV-2 [9, 10].

COVID-19 course has not been shown to be worse in pregnant women. Pregnant women are often tested for SARS-CoV-2 infection at admission for hospital delivery. According to this may explain the high proportion of asymptomatic cases found among pregnant women in different countries. In addition, infants and newborns have been described as more vulnerable to severe COVID-19 than other pediatric groups [11, 12]. Although a low mortality rate (0.006%) has been reported for this group in most cases [13, 14]. Among the COVID-19 cases with serious illness and death and the rates of people with underlying health conditions are remarkable. Primary health conditions reported among COVID-19 patients and admitted to the intense care unit (ICU) include hypertension, diabetes, cardiovascular disease, chronic respiratory disease, immunocompromised status, cancer, and obesity. A high proportion of long-term care facilities and nursing homes in Europe and the world are also severely affected by COVID-19. Consequently, high morbidity and mortality and high rates of absenteeism due to SARS-CoV-2 infections have been observed in residents [15-17]. In a systematic analysis study, 6007 articles, 212 studies from 11 countries/regions involving 281 461 individuals were analyzed (the mean age 46.7 years, and female-male ratio 49.2%-51.8%). Older age, male gender, diabetes, and hypertension were also associated with higher mortality with severe COVID-19, and the mortality rate was 5.6% and severe disease rate was 22.9% [5].

Health-care workers are at high risk of covid-19. Higher rates of cases are detected in contrast to other segments of society. This risk is thought to be caused by their exposure to higher concentrations of the virus. Since healthcare workers are younger and have fewer comorbidities, a milder disease picture is generally observed. Despite that, a large number of health-care workers died due to Covid-19. Mistakes in the use of personal protective equipment, problems with compliance with hand hygiene, intensive work, deficiencies related to hospital organization are factors that increase the risk of health-care workers [7]. Health-care worker's risk of Covid-19 transmission has been associated with the misuse of personal protective equipment during contact. In one study, 2% of the health-care workers who came into contact with Covid-19, and post-contact findings appeared within an average of 3.6 (0-17 days) days. In contamination, male gender, comorbidity, high-risk contact, and auxiliary personnel were identified as factors that increase the risk [18].

In a study, in our country, inappropriate use of personnel protective equipment, staying in the same personnel break room as an HCW without a medical mask, consuming food within, and failure to keep a safe social distance from an HCW were statistically significant risk

factors for infection [19]. One of the studies concluded in our hospital, it was found that approximately half of the health-care workers with Covid-19 were infected with their colleagues in social areas (unpublished data).

The elderly in long-term care (LTC) and their caregiving staff are at elevated risk from COVID-19. Coronavirus disease (COVID19)-related deaths in LTCF residents represent 30-60% of all COVID-19 deaths in many European countries [20].

In all epidemiological studies, the reliability of the data is low due to the lack of genome data of the virus, the fact that many asymptomatic cases can be contagious, and the studies are generally conducted using cross-sectional data.

PATHOGENESIS

The high infectivity of the virus, the lack of effective antivirals and vaccines, and potentially large asymptomatic populations have made the management of COVID-19 extremely difficult. Continuous efforts to better understand the pathogenesis of this disease, in addition to rapid medical interventions, will undoubtedly shed light on the management of the growing pandemic.

SARS-CoV-2 first affects the respiratory tract cells and the first proliferation site is the nasal mucosa. Viral load reaches its highest level at the onset of symptoms, but its spread (viral shedding) begins about 2-3 days before symptoms. Clinical course viral load is determined by the complex processes of infective dose and immune system response. The virus binds to cells with the spike S-protein and its main receptor is the angiotensin-converting enzyme 2 (ACE-2) receptor [21].

In the disease course, COVID-19 of viral replication in the lower respiratory tract, and generates secondary viremia, followed by an extensive attack against target organs. SARS-CoV-2 extensive attack against target organs that express ACE2, such as heart, kidney, gastrointestinal tract [22]. When SARS-CoV-2 infects cells expressing the surface receptors angiotensin-converting enzyme 2 (ACE2). Transmembrane protease serine 2 (TMPRSS2) activates viral S protein (especially Furin-like cleavage region) and cleaves the ACE2 receptor to facilitate viral binding to the host cell membrane. This binding triggers endocytosis allowing SARS-CoV-2 to enter the cell type in the virion cell membrane. The virus enters the host cell via endocytosis releases its RNA, and uses cell machinery to replicate itself and assemble more virions. Bronchial epithelial cells, type I and type II alveolar pneumocytes, and capillary endothelial cells are infected, an inflammatory response ensues.

The active replication release of the virus causes the host cell damage and release damage-associated molecular patterns (ATP, nucleic acids, and caspase proteins). Antagonism of the interferon (IFN- α and IFN- β) response aids viral replication, resulting in increased release of pyroptosis products that can further induce aberrant inflammatory responses. These are recognized by neighboring epithelial cells, endothelial cells, and alveolar macrophages, triggering the generation of pro-inflammatory cytokines and chemokines (including IL-6, IP-10, macrophage inflammatory proteins, MCP1...). All these proteins attract monocytes, macrophages, and T cells to the site of infection, promoting further inflammation (with the addition of IFN γ). Continued inflammatory response results in

alveolar interstitial mononuclear inflammatory infiltrate and edema develops and appears as ground-glass opacities on radiological imaging. In the late stage, thickened interstitium, hyaline membrane formation, the influx of monocytes and neutrophils, increased vascular permeability compatible with early-phase acute respiratory distress syndrome (ARDS) [19, 23].

When the immune response is excessive, it causes a cytokine storm with excessive production of proinflammatory cytokines in the lungs. This response can effectively lead to multiple organ damage in other organs. In addition, non-neutralizing antibodies produced by B cells may exacerbate antibody-dependent enhancement (ADE) organ damage. This process is mainly observed as clinical worsening observed 7-14 days following the onset of the disease. These findings show that the disease symptoms are particularly related to immune response, apart from viral damage. In severe and critically ill patients with COVID-19, two distinctive features of progressive increase in inflammation have been recognized. Possible pathways contributing to hyperactivation and hyperinflammation of monocyte-derived macrophages in COVID-19. Delayed type I interferon production, leading to increased cytopathic effects and greater perception of microbial threats, promote the increased release of monocyte chemoattractants by alveolar epithelial cells, leading to the continuous accumulation of monocytes into the lungs. Monocytes differentiate into proinflammatory macrophages through Janus kinase (JAK) activation. Activated natural killer (NK) cells and T cells further promote the recruitment and activation of macrophages through the production of granulocyte - macrophage-colony-stimulating factor (GM-CSF), tumor necrosis factor (TNF), and interferon-(IFN γ). The binding of Fc receptors (FcRs) by anti-spike protein IgG immune complexes may contribute to the increased inflammatory activation of monocyte-derived macrophages. Activated monocyte-derived macrophages contribute to the COVID-19 cytokine storm by secreting large amounts of pro-inflammatory cytokines [24].

Several factors may contribute to the hypercoagulability in COVID-19 patients. Certain cytokines including IL-6 could activate the coagulation system and suppress the fibrinolytic system. In the setting of COVID-19, activation of coagulation leads to microthrombus formation. COVID-19 patients elevated levels of D-dimer and fibrinogen associated with poor prognosis.

Lymphopenia is an important feature of patients with COVID-19. Lymphopenia is more common in patients with severe COVID-19, and this is an important sign of a poor prognosis [25, 26]. Declining lymphocyte groups are especially T lymphocytes and NK cells. Showed that T-lymphocyte count was inversely proportional to TNFa, IL-6, and IL-10 levels in particular and that an increase in inflammatory cytokine levels may promote depletion of T-cell populations along with disease progression [27]. Activation of CD14+CD16+ inflammatory monocytes was associated with an increase in IL-6, one of the key cytokines in the cytokine storm [28].

The clinical course of SARS-CoV-2 infection can be divided into three stages: the viremia stage, the acute stage (Immune response stage), and the progression or recovery stage. Patients with appropriate immune functions and without obvious risk factors (old age, comorbidities, genetic factors, etc.) can generate effective and sufficient immune responses to suppress the virus in the first or second stage without an excessive immune reaction. In contrast, patients with immune dysfunction may have a more severe clinical picture, intensive care admission, and a higher risk of death. There are no proven effective antivirals. Therefore, it mainly focuses on the close monitoring of disease stages and the application of ways of

stopping or slowing the progression of the disease (IL-6 inhibition, corticosteroid, immune plasma). In contrast, in a healthy immune response, the initial inflammation draws virus-specific T cells to the site of infection and they can eliminate infected cells before the virus spreads. Neutralizing antibodies in these individuals can block viral infection and alveolar macrophages recognize neutralized viruses and apoptotic cells and clear them by phagocytosis. All of these processes result in recovery by causing the virus to be cleared and minimal lung damage [19, 28].

In a post-mortem study of 10 consecutive patients who died of COVID-19 in Germany (mean age 79, 70% male, mean time between hospitalization and mortality 7.5 days), significant ARDS findings were found in the lungs, especially in the middle and lower lobes. Organizing-stage diffuse alveolar damage with pronounced fibroblastic proliferation, partial fibrosis, pneumocyte hyperplasia leading to interstitial thickening and collapsed alveoli, and patchy lymphocyte infiltration was the predominant finding.

In a post-mortem study of 10 consecutive patients who died of COVID-19 in Germany (mean age 79, 70% male, mean time between hospitalization and mortality 7.5 days), significant ARDS findings were found in the lungs, especially in the middle and lower lobes. Neutrophil infiltration was also detected in five cases with suspected aspiration and secondary infection [29].

Grifoni et al. Found SARS-CoV-2-specific CD8 and CD4 cells between 70-100% in 20 COVID-19 patients. CD4 cell response was correlated with the magnitude of the IgG response to spike protein. Interestingly, in the study, CD4 T lymphocytes reacting with SARS-CoV-2 were detected in 40-60% of those who were not in contact with the virus. This finding suggests a cross-response. These findings may be related to some people and children having milder COVID-19 disease [30]. Virus-specific IgM and IgG are detectable in serum between 7 and 14 days after the onset of symptoms. Viral RNA is inversely correlated with neutralizing antibody titers. Higher titers have been observed in critically ill patients, but it is unknown whether antibody responses somehow contribute to pulmonary pathology. The SARS-CoV-1 humoral response is relatively short-lived, and memory B cells may disappear altogether, suggesting that immunity with SARS-CoV-2 may wane 1-2 years after primary infection [31].

Non-neutralizing virus-specific IgG facilitates the entry of virus particles into cells expressing the Fc receptor (FcR), particularly macrophages and monocytes, and can lead to inflammatory activation of these cells. This phenomenon is called antibody-dependent enhancement (ADE), it is a condition that needs attention for immunoglobulin treatments and vaccine studies [32].

CONCLUSION

The Covid-19 pandemic cannot be expected to end soon. It has been understood that personal protective measures (mask, social distance, and hand hygiene) are effective methods against pandemics. There are many uncertainties regarding pathogenesis. Studies on this subject provide important findings on treatment and vaccination. Learning to live with the virus and accessing new information about pathogenesis will be the primary goal of science.

ABSTRACT

The main transmission routes of SARS-CoV-2 are through respiratory droplets and close contact with the index case but other possible routes are also reported. Although the virus may spread during aerosol-generating procedures, the probability of airborne transmission in other circumstances is controversial. Experimental studies demonstrated that SARS-CoV-2 remained viable in aerosols and on fomite surfaces up to 72 hours. However, no reports directly demonstrated transmission from the fomites. SARS-CoV-2 RNA was isolated in various biological specimens but currently, there is no report demonstrating direct transmission of SARS-CoV-2 apart from respiratory secretions except for two cases of vertical transmission.

The type, time, and duration of exposure, application of preventive measures, and the amount of the virus are among the most important predictors of the risk of transmission. Infectiousness begins approximately 3 days before symptom onset and peaks on the day of onset. The risk of transmission remains high in case of exposure to the index case within 5 days of symptom onset and is thought to continue until to 10-20 days depending on the severity of the disease and presence of underlying immunosuppressive diseases.

Although the preventive measures may differ according to public and healthcare settings the main strategy is to accept everyone as potential COVID-19 patients. In public settings, everyone should be encouraged to wear a facemask, maintain social distance, apply hand hygiene, avoid touching mouth, nose, and eyes, keep clean high touch areas, and obey isolation rules in case of illness or contact with COVID-19 patient. Every

healthcare center should redesign the structuring of its facility to maintain the physical distance and isolate COVID-19 patients. The administration should consider making arrangements regarding surgical and invasive procedures, outpatient and inpatient clinics in terms of COVID-19.

Patients and visitors should wear a facemask. Healthcare workers who care for patients with suspected or confirmed COVID-19 should wear personal protective equipment.

INTRODUCTION

At the end of 2019, a new virus later named as SARS-CoV-2 was thought to be transmitted firstly in a seafood market where live animals were sold, in Wuhan. Later on, person to person transmission was reported to be the main route of spread [1]. The routes of transmission and prevention strategies will be mentioned in this chapter.

ROUTES OF TRANSMISSION

Although the main transmission routes for SARS-CoV-2 are through droplets and close contact, many other ways also are reported [2-4]. Other possible routes consist of airborne, fomite, fecal-oral, bloodborne, vertical, and animal to human transmission [2].

Droplet and Contact Transmission

The primary means of transmission is via respiratory droplets ($> 5 \mu\text{m}$, not traveling more than 1-2 meters). Direct, indirect, or close contact with infected respiratory secretions or droplets may lead to transmission. Infected patients may spread the respiratory droplets including SARS-CoV-2 during coughing, sneezing, singing, or talking to people in a close range contact. The droplets may reach directly the mucous membranes (mouth, nose, or eyes) of a susceptible host [2, 4]. Indirect contact transmission may occur after contact with a contaminated object/surface and then spreading the virus to eyes, nose, or mouth by touching [3].

Airborne Transmission

Airborne transmission occurs when aerosols (droplet nuclei $< 5 \mu\text{m}$, traveling more than 2 meters) containing the microorganism suspended in air disseminate over a distance. Although SARS-CoV-2 may spread during aerosol-generating procedures; the probability of airborne transmission in other circumstances is controversial [2]. Various experimental studies evaluated this issue: some revealed that aerosols may develop during coughing or talking varying according to the modes of practices (such as loud speech, shouting), the others demonstrated that SARS-CoV-2 RNA may remain in aerosols generated via high-powered jet nebulizers for up to 3-16 hours and some investigators identified viral RNA in ventilation

systems or air of COVID-19 patients' rooms. But the presence of a viable virus in air samples is reported only in a limited number of studies [2, 5-11]. Although outbreak reports in a closed, crowded, and poorly ventilated area (such as restaurants, buses) may suggest the probability of airborne transmission, the transmission in these cases may also be associated with droplet and fomite surfaces [2, 12, 13].

Until further research clarifies the possibility of airborne transmission in SARS-CoV-2 infection in the community, it would be reasonable to accept that the virus may be transmitted via droplet nuclei during aerosol-generating procedures.

Fomite Transmission

Respiratory droplets may contaminate the surfaces and the objects around the patients and touching mouth, eyes, or mouth after contact with these surfaces may lead to indirect transmission of the virus [2]. The virus may be disseminated all over the ward including bed handrails, doorknobs, trash cans, computer mouse, floor, shoe soles, and other surfaces. However, the detection of the nucleic acid over these surfaces does not indicate that the virus is viable [14]. The environment temperature and humidity and the type of surfaces are predictors of stability of the virus over the fomites [2]. Van Doremalen et al., in their experimental studies demonstrated that SARS-CoV-2 remained viable in aerosols, on copper, cardboard, plastic, and stainless steel up to 3, 4, 24, and 72 hours respectively while the virus titer reduced with time [7]. Although many studies evaluated the survival of the virus on environmental surfaces there are no reports directly demonstrating transmission from the fomites [2].

Other Modes of Transmission

SARS-CoV-2 RNA was isolated in other biological specimens such as urine, feces, semen, or ocular secretions, but the presence of viable viruses was reported only in some studies [11, 15-18]. Although there are various hypotheses, currently there is no report demonstrating direct transmission of SARS-CoV-2 via these routes [2]. Viral RNA was also detected in blood but the role of transmission via blood and blood products is controversial [15-19].

Nasopharyngeal specimens, umbilical cord blood, and placental specimens of neonates born to infected mothers were demonstrated to include viral RNA, however evidence of intrauterine transmission is sparse [20-22].

World Health Organization (WHO) in its scientific brief reported that viral RNA fragments have been found in breast milk samples of infected mothers. But since the viable virus could not be detected, WHO recommends that mothers with suspected or confirmed COVID-19 should be encouraged to breastfeed [23].

Dogs, cats, and farmed minks have been reported to be infected by humans but the probability of transmission of COVID-19 from infected animals to humans is unclear [24-26].

Period of Infectiousness

With the first report of transmission of SARS-CoV-2 after contact with an index case during the incubation period in Germany, the variability in the probability of transmission during COVID-19 has become a matter of interest [27]. He et al., in their experimental study demonstrated that infectiousness begins 5–6 days before symptom onset and peaks on the day of onset. Upon observation that 1% of transmissions would occur 5 days and 9% of transmissions 3 days before symptom onset, they concluded that 3 days before symptom onset is critical in terms of transmission [28]. In another study performed in Taiwan, 2500 close contacts of 100 patients were analyzed and a secondary clinical attack rate was found to be higher in case of exposure to the index case within 5 days of symptom onset [29].

Although viral RNA may be detected in biological specimens after months of SARS-CoV-2 infection, Wölfel et al., demonstrated that this may not mean that the virus is infectious if the RNA level was $< 10^6$ copies/mL [30, 31]. On the other hand viable viruses although not replication-competent, may be isolated after more than 10 days in some cases depending on the severity of the disease and underlying immunosuppression [30, 32, 33]. According to the Centers for Disease Control and Prevention (CDC), patients with mild to moderate disease and with more severe disease or immunosuppression most probably are not infectious for longer than 10 days and 20 days after symptom onset, respectively [33].

PREVENTION STRATEGIES

The type, time, and duration of exposure, application of preventive measures, and the amount of the virus are among the most important predictors of the risk of transmission [3, 28, 29]. The risk of transmission is high among household contacts where the secondary attack rate ranges between 15-38% [34, 35]. Besides household contacts and gathering activities, traveling with an index case without preventive measures or indoor activities are associated with a high risk of transmission. Since the probability of neglect of wearing a facemask or social distancing may be high while eating or drinking in indoor environments, the risk for transmission remains an important concern [36, 37]. Outdoor activities carry a low risk for transmission except for close contact with an index case [3].

The best way of prevention of transmission includes testing the suspected individuals, isolating the infected cases, determining all close contacts, and self/quarantine them [3].

The prevention strategies can be classified under 2 subgroups: public and healthcare settings.

Public Settings

On individual and public health basis, these measures should be applied by everyone in the public:

- *Washing hands with soap and water for at least 20 seconds or rubbing hands with hand antiseptic containing at least 65% alcohol, after being in a public area, before*

or after touching the face, after handling the mask, after sneezing or coughing, after touching surfaces, before eating or preparing food, after going to the restroom

- *Avoiding touching eyes, nose, or mouth*
- *Avoiding close contact (maintaining a distance of 1-2 meters between people)*
- *Wearing a mask (facemask or cloth covering) covering the mouth and nose in public settings*
- *Using tissues to cover mouth and nose during coughing and sneezing and throwing them into the trash can or bent elbow when coughing or sneezing*
- *Cleaning and disinfecting touched surfaces daily [38].*
- *Individuals having close contact (< 2 meters for ≥ 15 minutes) with people having COVID-19 symptoms (laboratory-confirmed or clinically compatible) 2 days before symptom onset and until discontinuation of isolation are accepted to have a high risk for exposure. They should quarantine themselves for 14 days after the last exposure, maintain social distance between people, self-monitor for symptoms of COVID-19 [39].*

Each country can make different arrangements to re-organize environmental conditions in schools, workplaces, prisons, dormitories, nursing homes, shopping centers, fitness centers, restaurants, and other indoor areas, and ameliorates travel conditions, taking into account the number of confirmed cases, current resources, and sociocultural characteristics.

Healthcare Settings

Every healthcare center should implement its prevention strategies to the utmost to protect its workers and patients. These measures should include some major principles:

General Principles

- Telemedicine policies should be implemented if possible, to eliminate the unnecessary admission of patients to the centers and transmission of SARS-CoV-2. Besides telemedicine, general information about the facilities' strategies during the pandemic period should be mentioned on the website. If the patients have to apply to the healthcare center, they should be questioned about the signs and symptoms of COVID-19. Patients without compatible symptoms should be advised to cover their mouth and nose with a facemask or cloth covering upon admission.
- Every healthcare center should redesign the structuring of the facility to maintain the physical distance, constitute separate entrances for patients admitted with signs and symptoms of COVID-19 and separate outpatient clinics, wards, or buildings for COVID-19 patients, and display (posters and visuals) information at the entrance to direct the patients to these designated areas.
- Posters and visuals should be placed at the entrance and in common places to mention the use of facemasks and proper hand hygiene.
- Rearrangements should be made to maintain social distance in strategic places such as waiting areas, elevators, and cafeterias to prevent crowding. Regular cleaning and disinfection of these areas should be provided.

- All staff in the institution should be educated in terms of prevention measures.
- The administration should consider postponing elective procedures, outpatient admissions, and surgeries if relevant and update the decisions when convenient.
- Patients and visitors should wear facemask or cloth face-covering upon arrival to the hospital. If facemasks or cloth coverings are not worn facemasks should be provided at the entry.
- Every patient admitted to the healthcare facility for any reason should be screened for COVID-19 signs and symptoms (the body temperature should be actively measured) and questioned for exposure to COVID-19 patients within the last 14 days upon entry. In case of suspicion, the patients should be transferred to a special area dedicated to COVID-19 patients.
- Restrictions to visitors should be applied. They should also be screened for COVID-19 symptoms and questioned for exposure to COVID-19 patients within the last 14 days. Those with symptoms and with a history of exposure should not be permitted to enter the healthcare centers and directed to the COVID-19 outpatient clinic.
- Environmental and engineering controls should provide adequate ventilation, structural design, environmental cleaning. Air conditioners should not be run in areas where more than one person is present.
- Commonly used and frequently touched surfaces (push buttons, door handles, etc.) should be cleaned and disinfected regularly. Equipment such as stretchers and wheelchairs used by patients should be disinfected after each patient use.
- Disinfection of devices such as phones, computers, etc. should be provided by the handler (70% of alcohol).
- Communication and transfer with paper, cardboard files, etc. should be minimized in the whole facility and online communication should be encouraged.
- All scientific and educational meetings should be held online at the utmost.

Outpatient Clinics

- Arrangements should be made to provide 1.5-2 meters of distance between healthcare workers (HCW) and patients in outpatient clinics.
- Alcohol-based hand antiseptics and substances required for the disinfection of the surfaces should be provided.
- The patients should wear facemasks and the HCWs should wear medical masks and goggles/face shields.
- Disinfection of common equipment after each use (70% alcohol) should be provided.

Inpatient Clinics

- All wards should be rearranged to place patients in a single room, if not possible, the patients should be separated by 2 meters from each other to prevent the transmission.
- COVID-19 patients should be followed up in a well ventilated private room with the bathroom placed within and the door closed. If isolation of the patient is not possible, confirmed COVID-19 patients may be cohorted.
- Inpatients should be provided facemasks. Patients may remove their masks when in their rooms but should put on when leaving their room, or when HCWs, other staff,

or visitors enter their room. Alcohol-based hand antiseptics should be available in every patient room and common areas.

- Equipment used for patients should be patient-specific and shared equipment should be disinfected (70% alcohol) after use.
- Patient rooms should be cleaned every day and in case of contamination.

Healthcare Workers

- Besides standard precautions, contact and droplet prevention measures should be taken during the care of suspected or confirmed COVID-19 patients.
- All HCWs who care for patients with suspected or confirmed COVID-19 should wear personal protective equipment (PPE). Standard PPE includes the use of a respirator or medical mask, goggles or face shield, a gown, and gloves.
- In conventional settings HCWs caring for patients with suspected or known COVID-19, should use a medical mask (CDC recommends the use of a medical mask or N95 or equivalent or higher level respirator; in case of respirator shortages, medical mask or reprocessed respirator can be used).
- Gloves and gowns are recommended in procedures carrying the risk of exposure to body fluids. They should always be changed after each patient contact. In case of heavy exposure to body fluids waterproof gowns may be preferred.
- HCWs should wear medical masks the day in the healthcare center including breakrooms or meeting areas since they may be exposed to asymptomatic or presymptomatic people.
- HCWs should avoid touching their face to eliminate the risk of self-contamination.
- Aerosol-generating procedures may lead to airborne transmission. These procedures include the following:
 - Endotracheal intubation and extubation
 - Manual ventilation before intubation
 - Noninvasive ventilation
 - Filter changes on the ventilator
 - Bronchoscopy (including mini bronchoalveolar lavage)
 - Cardiopulmonary resuscitation
 - Sputum induction
 - Open suctioning of airways
 - Tracheotomy
 - High-flow oxygen
 - Nasal endoscopy
 - Upper endoscopy (including transesophageal echocardiogram)
 - Use of nebulizer
 - Colonoscopy
 - Autopsies
- Aerosol-generating procedures should be carried out in a negative pressure room if possible or in a single room with the door kept closed and the room should be ventilated after the procedure.
- HCWs should wear an N95 (or equivalent or higher level) respirator, goggles or face shield, gloves, and gowns during these procedures. If N95 respirators are not

available reprocessed respirators should be reused or a face shield or medical mask should be put on the respirator as a cover for extended use.

- Respirators with exhalation valves are not recommended.
- Hand hygiene should be performed before and after patient contact, after exposure to infectious material, before wearing and after removing all PPE.
- *Alcohol-based hand antiseptics containing 65-95% of alcohol should be used for hand hygiene or the hands should be washed with soap and water [40-45].*
- *Although* nasopharyngeal specimen collection is not considered as aerosol-generating procedure CDC recommends the use of respirator, face shield or goggles, gloves, and gowns [40].
- Exposure of contaminated material to HCW's eyes nose or mouth during aerosol-generating procedures is defined as high-risk exposure if the HCW has no any PPE.
- The HCW should be excluded from work for 14 days after last exposure in case of a prolonged and close contact (< 2 meters for ≥ 15 minutes) with a confirmed COVID-19 patient before 2 days of symptom onset until the end of the isolation period:
- if the HCW does not wear a medical mask or respirator or
- if the HCW does not have eye or face protection when the patient does not wear a mask or
- if the HCW does not wear all PPE during aerosol-generating procedures (any duration of the contact is accepted as prolonged and close contact)
- In the case of the staffing shortage, HCW with a history of exposure can be allowed to work as long as he/she obeys preventive measures strictly. The HCW should monitor him/herself for signs and symptoms for the next 14 days after exposure.

Surgical Procedures

- Elective surgeries should be postponed. If the surgical procedures can not be postponed patients should be screened for COVID-19 signs and symptoms and in the presence of symptoms they should be tested for COVID-19 by molecular methods. If the suspicion level for COVID-19 is high and the nasopharyngeal swab test result by polymerase chain reaction (PCR) is negative, a second test may be performed. Some centers may consider testing all patients before surgery independent of symptoms. However, delays in results and the probability of negative results during the incubation period should be taken into consideration.
- COVID-19 patients should wear a medical mask and transport staff should apply droplets and contact prevention measures during transfer to the operating room.
- All HCWs in the operation team should wear N95, FFP2, or equivalent or higher level respirators, waterproof sterile gown, sterile gloves, goggles/face shield during the operation of a suspected or confirmed COVID-19 patients.
- Even if COVID-19 is excluded at the end of the evaluation, general contact and droplet precautions should be taken in operating rooms during the pandemic period.

Environmental Cleaning and Disinfection

- Surfaces should be cleaned with water and detergent firstly. Then application of 0.1% (1000ppm) sodium hypochlorite or 70-90% ethanol is effective. In the case of contamination with blood or body fluids, a concentration of 0.5% (5000ppm) sodium hypochlorite should be used.

- For sensitive surfaces and screens, 70% of alcohol can also be used for surface disinfection.
- Cleaning staff should use PPE [40-45].

CONCLUSION

COVID-19 pandemic continues all over the world. Although investigations in the fields of vaccination and treatment continue, the pandemic is not expected to end in a short time. Except for aerosol-generating procedures, the main route of transmission is thought to be through droplets and close contact. Considering all these factors, the use of masks, social distance, and hand hygiene should be provided based on the public setting. In the healthcare settings, except for aerosol-generating procedures, HCWs should take standard, contact, and droplet precautions.

²Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty,
Department of Infectious Diseases and Clinical Microbiology, Istanbul, Turkey

ABSTRACT

COVID-19, named by the World Health Organization in February 2020, is an infectious and fatal disease that first started in China in December 2019 by the determination of pneumonia cases secondary to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and has been rapidly spreading all over the world since then. Although COVID-19 was first thought to be a disease manifested only by respiratory symptoms at the beginning of the outbreak, we learned in time that it is a disease that can develop symptoms in a wide spectrum from asymptomatic infection to cardiovascular complications. Experience in the diagnosis, clinical characteristics and treatment of COVID-19 has been accumulating in the time since it is a new disease. The severity of the disease might be variable according to the viral load received and the immune response of the individual. The frequency of asymptomatic disease is substantially high. The most commonly seen complaints in symptomatic disease are fever, cough, fatigue, and myalgia, while nausea, vomiting, and loss of taste and smell can also be seen. The longer the duration of the symptoms, the higher is the risk of developing a more severe disease necessitating hospital admission and intensive care, and invasive ventilation. Solid knowledge of clinical symptoms and diagnostic tests is important since early diagnosis may prevent the spread and intensification of the disease.

INTRODUCTION

COVID-19 infection has caused a fatal outbreak which started in the Wuhan City of China and spread all over the world from there. COVID-19 developed secondary to SARS-CoV-2 has been officially declared to be a pandemic by the World Health Organization on March 11, 2020 [1]. The clinical picture is variable from a completely asymptomatic one to a rapidly destructive course. The clinical picture of COVID-19 including the incubation period, asymptomatic patients, symptoms, risk factors for severe disease, and complications will be reviewed in this chapter.

INCUBATION PERIOD

The incubation period of COVID-19 disease is 2-14 days in 98% of the patients with a mean duration of 4-5 days [2-5]. The symptoms were reported to begin in 11.5 days (8.2-15.6) in 97.5% of the patients in a modeling study including 181 patients with a definitive diagnosis of Covid-19, while the mean duration of incubation was determined as 5.1 days [5]. Typically, the period from the initiation of symptoms and the development of the severe disease is a week [2]. The mean duration of incubation was predicted to be 5 days (4.4-5.6 days) in an analysis performed at a center out of Wuhan including 158 definitive cases [6].

It was reported in a striking study that the duration between the exposure and initiation of contagiousness (latent period) might be shorter [7]. Another study revealed that the viral load was high 2-3 days before the symptoms with a peak value of 0.7 days before the start of symptoms [8]. Therefore, it is important to screen the contacts of patients diagnosed to have COVID-19 and to consider the period before the start of symptoms.

ASYMPTOMATIC INFECTIONS

Asymptomatic infections and infections that are not symptomatic at the time of the diagnosis (pre-symptomatic) have been documented thoroughly in several studies [9-21]. Knowledge of the frequency of asymptomatic infections is crucial to understand the spread of the virus and the dynamics of the disease. Asymptomatic infections were reported to constitute 40-45% of SARS-CoV-2 infections in a study based on the data obtained from three major cohort studies [21]. However, no longitudinal follow-up was performed in that above mentioned and other similar studies to observe the development of symptoms. The prevalence of asymptomatic infections and the diagnosis of pre-symptomatic infections has yet to be understood since asymptomatic individuals are not routinely tested. The definition of asymptomatic is variable in several studies due to the specific symptoms evaluated. For example; 328 out of 634 (51.7%) cases were found to be asymptomatic in the Diamond Princess cruise in which all passengers and crew were quarantined in the Yokohama City of Japan. Considering the incubation period varying between 5.5 and 9.5 days, the authors calculated the actual rate of asymptomatic cases as 17.9% [14]. The rate of asymptomatic cases was 26% in an observational cohort study conducted on 199 infected patients in an inpatient treatment center in South Korea [22]. The percentage of patients tested positive for

SARS-CoV-2 but without any symptoms was reported to be 44% in a screening study performed in Ireland; however, some of them might be pre-symptomatic [20]. Higher rates of asymptomatic cases have been reported in some studies. For example, 29 out of 210 pregnant women (14%) admitted to two New York hospitals for childbirth at the time of the peak of the pandemic were tested to be positive for SARS-CoV-2 using polymerase chain reaction (RT-PCR). Other than those, four women who were tested positive for SARS-CoV-2 had a fever and other symptoms. Therefore, 29 out of 33 women with a positive test for SARS-CoV-2 (88%) were asymptomatic at the time of presentation to the hospital [19]. The rate of asymptomatic patients was around 20-40% in all those studies, while this wide range might be due to the different properties of the populations analyzed.

Asymptomatic patients might present clinically objective findings [10, 23]. An example of this is a study including 24 patients with asymptomatic infection; 50% of the patients had typical CT involvement of COVID-19 and another 20% of them had atypical radiological abnormalities [10]. In another study including 55 patients with asymptomatic infection, pneumonia was detected by CT in 67% of the patients at presentation; only two patients developed hypoxia, and all patients recovered (23). Cases that were asymptomatic at the time of the diagnosis as the cases mentioned above can be classified as pre-symptomatic infections. The initiation of symptoms was seen as a mean of 4 days (3-7 days) after the first positive RT-PCR test in a study performed [24].

CLINICAL PRESENTATION

Differentiating the first symptoms of COVID-19 from other viral upper respiratory infections is almost impossible. However, with the accumulating experience, it has now been acknowledged that COVID-19 infection is not a disease of the respiratory tract alone, but it is a disease involving many organs and is manifested with different symptoms according to the organ involved and the degree of the immune response [25].

The most frequent symptoms seen in COVID-19 infection are as follows [3, 26-31]:

- Fever
- Cough
- Dyspnea or difficulty in breathing
- Fatigue, weakness
- Muscle pain (myalgia) or the ache of body parts
- Headache
- Loss of smell (anosmia) and taste (ageusia)
- Sore throat
- Nasal congestion
- Nausea or vomiting
- Diarrhea

Symptoms vary according to the severity of the disease. For example, fever, cough, and dyspnea were reported to be more common in hospitalized patients with COVID-19 compared to patients with less severe disease and thus not admitted to the hospital. Atypical

symptoms might be seen in the elderly and patients with comorbidities, and the manifestation of fever and respiratory symptoms might be delayed [32, 33]. Fever was reported to be present in 44% of 1099 patients at admission to the hospital and 89% had fever rising after admission in a study performed in China [3]. No differentiation between mild and severe cases and prediction of the clinical course can be made according to the presence or absence of fever and cough [34, 35]. Dyspnea was demonstrated in larger studies to be a powerful predictor of severe disease. Respiratory distress might be developed generally during the second week of the disease and might progress to hypoxemia [3]. A clinical picture of viral pneumonia predominates and may include fever, cough, and hypoxia. Imaging of the lungs reveals bilateral ground-glass imaging and infiltrations [36].

Fatigue, headache, and myalgia are the most commonly reported symptoms with an incidence of 15-40% among outpatients with COVID-19 [37, 38]. These symptoms, although frequently disturbing, are not indicators of a severe clinical picture. Headache is bilateral with an intermediate severity and experienced in the temporo-parietal, frontal or periorbital areas [39]. A part of the patients may present with gastrointestinal symptoms such as nausea, vomiting, or diarrhea before the development of fever and lower respiratory tract signs and symptoms [31]. Diarrhea and nausea and vomiting were observed in 24% and 19%, respectively among the first 393 patients admitted to two hospitals in New York [40]. Enteric symptoms are generally seen together with fever and respiratory tract complaints. Among the 18,605 patients presenting to the hospital in the United Kingdom, 29% had enteric symptoms, generally together with respiratory symptoms, while only 4% of all patients reported enteric symptoms alone [38]. Symptoms of the upper respiratory tract such as nasal congestion, nasal discharge, sneezing, and sore throat are quite rare in COVID-19 infection.

On the other hand, loss of taste (ageusia) and smell (anosmia) has been reported widely before the start of the symptoms in young women and young and middle-aged individuals who needed no hospitalization [41, 42]. The largest study on this subject revealed the loss of smell in 1754 (87%) and loss of taste in 1136 (56%) out of 2013 patients [43].

Although most symptoms of COVID-19 are common in other respiratory tract infections or viral diseases, anosmia seems to be a more specific sign of COVID-19 [42]. In conclusion, the presence of anosmia and ageusia demonstrate no severe disease; however, they might be important indicators of SARS-CoV-2 infection.

CLINICAL COURSE OF THE DISEASE

The severity of COVID-19 infection might be variable from mild to critical. The course is frequently mild [9, 26, 27, 28, 41, 44]. Currently, there is no definitively accepted clinical classification for COVID-19. The following classification including four categories has been used by some authors [45].

- Mild cases: symptomatic cases with no observed pneumonia with imaging.
- Ordinary cases: Fever and signs of pneumonia with imaging.
- Severe cases: Dyspnea, hypoxia ($\text{SpO}_2 \leq 93\%$), abnormal blood gas analysis $\text{PaO}_2 < 60\text{mmHg}$, $\text{PaCO}_2 > 50\text{mmHg}$).

- Critical cases: Respiratory failure necessitating mechanical ventilation, shock, other organ failure requiring admission to ICU.

A similar classification was used in the study of Chinese Disease Control Center including 44,500 confirmed infections; however, item 1 and 2 were combined, such as;

- Mild to intermediate disease (pneumonia is mild or absent), reported in 81%
- Severe disease (dyspnea, hypoxia or findings such as more than 50% lung involvement in imaging studies in 24 to 48 hours) in 14%
- Critical disease (clinical pictures such as respiratory failure, shock, or multiorgan dysfunction), reported in 5%.

No death was seen in non-critical patients in that study. The General case fatality rate was reported to be 2.3% [46]. Asymptomatic/mild-intermediate disease, respiratory failure and death were seen in 80.5%, 19.5% and 5.5%, respectively in a meta-analysis including 38 studies [47]. The rate of critical disease and death are higher in hospitalized patients [34, 35, 48, 49]. Some 665 patients (24%) died or were referred to nursing care in a study including 2741 patients hospitalized due to COVID-19 in New York [35]. The clinical course of the disease and death rates are variable according to the region. The rate of admission to the intensive care unit was 12% among all cases with COVID-19 and 16% among all patients hospitalized in Italy with an estimated case fatality rate of 7.2% in mid-March [50, 51]. In contrast, the estimated case fatality rate in mid-March in South Korea was 0.9% [52]. This might be due to the demographic variability of the infections such as the median age of the infected patients (64 years in Italy and 40 years in Korea).

CLINICAL PROGRESSION

The clinicians must be careful on clinical progression since it generally occurs a week after the initiation of the disease. Mean duration between the initiation of symptoms to development of dyspnea among patients who develop severe disease has been reported to be 5-8 days, between the start of the disease to the development of acute respiratory distress syndrome (ARDS) as 8-12 days and from the initiation of symptoms or the disease to the admission to intensive care unit (ICU) as 10-12 days in the studies performed [27, 28, 32, 41]. The rate of admission to ICU among hospitalized patients has been reported to be 26-32% [28, 41]. The mortality rate in patients admitted to the ICU, depending on the study and the properties of the population is 39-72% [27, 30, 32, 41]. The mean duration of hospital stay in surviving patients has been 10-13 days in the studies performed [3, 28, 30].

RISK FACTORS FOR SEVERE ILLNESS

Advanced age; is a powerful risk factor for severe disease, and the development of complications and mortality [3, 28, 30, 46, 53, 54, 55]. Mortality rate among more than 44,000 confirmed COVID-19 cases in China was reported as 14.8%, 8%, 3.6%, 1.3%, 0.4%

and 0.2% in patients aged 80 years and above, 70-79 years, 60-69 years, 50-59 years, 40-49 years and <40 years, respectively [56, 57]. Advanced age has been defined as a serious risk factor for severe disease and death rates in recent literature from all over the world. One example of these studies is a large one evaluating the outbreak in 20.133 patients in the United Kingdom and the mean age of 5.165 patients who died in the hospital (26%) due to COVID-19 was reported as 80 years in that study [58]. A dramatic increase was observed among the group of patients with advanced age among 5700 patients in New York and the mortality rate reached up to 61% (122/199) in males and 48% (115/242) in females with the age of more than 80 years [34].

The mortality rate was markedly higher among the elderly patients (>63 years) compared to young patients (36% and 15%) in 1.591 patients admitted in the ICU in Italy. The mortality rate in 362 patients with an age above 70 years was reported to be 41% [59].

Other risk factors: Initial studies from China revealed that diseases such as hypertension, cardiovascular disease, and diabetes were associated with severe disease and mortality [3]. Later, other studies from various regions have demonstrated that the risk of development of severe disease and mortality was higher in patients with comorbidities [32, 46, 35, 60, 61, 62, 63].

- Cardiovascular disease
- Diabetes mellitus
- Hypertension
- Chronic lung disease
- Cancer (in particular hematologic malignancies, lung cancer, and metastatic disease)
- Chronic kidney disease
- Obesity
- Smoking

Individuals with hypertension, cardiovascular disease, and chronic lung disease were reported to carry a higher risk of having a severe course in a meta-analysis evaluating 46.248 confirmed cases of COVID-19 in eight studies [64]. The mortality rate was 12-fold among patients with reported comorbidities compared to the ones with no comorbidities in a study from the United States of America including 300.000 confirmed COVID-19 cases [65].

In conclusion; advanced age and presence of comorbidity, alone or combined, are marked risk factors for severe disease and mortality.

COMPLICATIONS

Patients with a mild course are generally not hospitalized. The treatment of most patients can be managed at home. The decision for hospitalization depends on the clinical picture, necessity of supportive care, potential risk factors for severe disease, and the ability of the patient for self-isolation. Patients with risk factors should be closely followed-up especially during the second week since there is a risk of advancement to severe disease. Patients with COVID-19 with initially mild symptoms may deteriorate during the first week [66]. Dyspnea was reported to develop mean five days after the start of the symptoms and admission to

hospital was required a mean of seven days after the initiation of symptoms in a study including 138 patients admitted to the hospital with pneumonia secondary to SARS-CoV-2 in Wuhan [28].

The most significant complications of COVID-19 can be defined as:

Respiratory Failure

Acute respiratory distress syndrome (ARDS) is the most important complication in patients with COVID-19 and might be observed a short period after the initiation of dyspnea. ARDS develops on day 8-14 in 10-20% of the patients [67, 68]. Non-cardiogenic pulmonary edema develops in those patients and mechanical ventilation might be required. Hypertension, diabetes mellitus, and cardiovascular and cerebrovascular diseases have been reported to be a risk factor for ARDS [68]. Retrospective studies on patients with critical illness established that initiation of dyspnea was average 6.5 days after the start of the disease; however, the development of ARDS was seen even in a shorter period after the start of dyspnea (mean 2 days) [28, 32, 41, 55]. Some 12-24% of the hospitalized patients required mechanical ventilation according to the studies performed in the USA [34, 35].

Cardiac and Cardiovascular Complications

Arrhythmia, acute cardiac damage, and shock are reported complications [28, 55, 69]. The rate of these complications was reported to be 17%, 7%, and 9%, respectively in a study [28]. On the other hand, acute cardiac damage and heart failure was seen in 77% (72/94) and 49% (41/83), respectively in a retrospective study evaluating 113 patients who died due to COVID-19 infection [69]. The development of cardiomyopathy was reported in one-third of the patients in a series including 21 severe cases admitted to the ICU in the USA [55].

Thromboembolic Complications

Coagulation disorders that complicate the clinical management of the disease are seen in some patients with COVID-19. These patients carry a high risk for arterial and venous thrombosis of small and large vessels due to hypercoagulation [70, 71]. SARS-CoV-2 directly invades endothelial cells and causes cell damage. Endothelial damage, microvascular inflammation, endothelial exocytosis, and/or endothelitis play a central role in the pathogenesis of acute respiratory distress syndrome and organ failure according to some experts [72, 73]. Induction of endothelial cells due to infection causes excess production of thrombin and fibrinolysis is prevented. Also, patients are prone to venous and arterial thromboembolic events due to hypoxia, increased inflammation, and immobilization. Commonly observed laboratory findings among hospitalized patients with COVID-19-associated coagulopathy are mild thrombocytopenia, increased level of D-dimer, fibrin degradation products, and prothrombin time. High levels of D-dimer have been highly associated with a higher death rate [70, 74, 75, 76]. Pulmonary embolism, deep venous

thrombosis, myocardial infarct, ischemic events, or systemic arterial embolism can be frequently seen in these patients. Cases with severe COVID-10 have been generally shown in the studies performed to be complicated with coagulopathies and DIC has been demonstrated in most cases of mortality.

Inflammatory Complications

A “cytokine storm” including an increase in the levels of inflammatory cytokines such as IL-1, IL-6, IL-8, and levels of TNF- α and IFN- γ is present in the pathogenesis of COVID-19 disease [77, 78]. Persistent high fever and high levels of inflammatory markers (i.e., D-dimer and ferritin) and increased proinflammatory cytokines have proven a marked inflammatory response on a laboratory basis and these laboratory values have been associated with critical and fatal diseases [27, 79, 80]. Levels of many cytokines such as C-reactive protein (CRP), ferritin, and IL-6 were reported to increase in severe disease in a meta-analysis [32]. Decreased interleukin-6 (IL-6) levels were revealed to be closely associated with treatment efficacy, while increased levels of IL-6 demonstrated exacerbation of the disease in a retrospective observational analysis including 69 cases with severe COVID-19 [81]. The authors concluded that the dynamic changes in the IL-6 levels could be used as a marker during the follow-up of the disease in patients with severe COVID-19. Finally, cytokine storm should be considered in patients with persistent fever despite treatment, increased D-dimer, ferritin, and CRP levels, decreased lymphocyte and platelet counts, increased fibrinogen levels, and deteriorated liver function tests. Early diagnosis of this clinical picture is substantial since it is a condition that needs emergency treatment. Patients demonstrating signs of severe COVID-19 infection should be daily monitored for markers of a cytokine storm. Other inflammatory complications and auto-antibody mediated signs have been defined other than the cytokine storm [82, 83]. Myasthenia gravis is one of them [82]. Guillain-Barré syndrome can be developed 5-10 days after the initial symptoms [84]. In addition, a multi-system inflammatory syndrome with similar clinical properties with Kawasaki disease and toxic shock syndrome has been defined in children with COVID-19. This syndrome, rarely reported in adults also has been characterized with markedly increased inflammatory markers and multi-organ dysfunction (especially cardiac dysfunction) and minimal pulmonary involvement [85].

Secondary Infections

Secondary infections don't seem to be a common complication of COVID-19, although the data is limited [86, 87]. The rate of the reported bacterial or fungal infections was 8% in a publication evaluating nine studies, mostly from China and they mainly included respiratory tract infections and bacteremia [86]. Possible invasive aspergillosis has been reported among the patients with ARDS secondary to COVID-19 and no immune suppression; however, the incidence of this complication is unknown [88, 89, 90, 91].

RECOVERY AND LONG-TERM SEQUELA

According to the World Health Organization (WHO), the period of recovery seems to be almost two weeks for mild disease and three to six weeks for the severe disease [92]. Nevertheless, the period of recovery varies based on age and previously present additional diseases in addition to the severity of the disease.

A survey on 350 patients with COVID-19 in the United States of America revealed that only 39% of the patients admitted to a hospital had a full recovery 14-21 days after the diagnosis [93]. Similarly, only 13% of 143 patients admitted to the hospital (7 of them were intubated) due to COVID-19 in Italy were without symptoms after a mean of 60 days starting from the initiation of the disease [94]. The most common persistent symptoms were fatigue (53%), dyspnea (43%), joint pain (27%), and chest pain (22%); however, none of the patients had a fever or acute findings of the disease. On the other hand, persistent severe disease together with persistent fever for weeks and pneumonia associated with underlying immunosuppression has been reported in another study [95].

Symptoms may persist for a long time also in patients with COVID-19 and milder symptoms [98, 96]. In a survey with 292 participants diagnosed to have COVID-19 and were treated on an outpatient basis, 65% of the patients reported being as healthy as before they had the disease 14-21 days after the diagnosis [96]. Individuals with full recovery recovered in a mean of 7 days after the diagnosis. The symptoms that patients most possibly continued to have 14-21 days after the diagnosis were cough (43%) and fatigue (35%).

As of the established data, a potential of respiratory insufficiency and the cardiac sequel has been suggested, although the evaluation of long-term sequela of COVID-19 has not been adequately evaluated yet [97-102].

LABORATORY FINDINGS

The most common laboratory findings seen in patients hospitalized with the diagnosis of COVID-19 are lymphopenia, high levels of serum aminotransferase, lactate dehydrogenase, and inflammatory markers (i.e., ferritin, C-reactive protein, and erythrocyte sedimentation rate), and abnormalities in coagulation tests. [28, 3, 40, 27, 30].

Lymphopenia is the most common laboratory finding of COVID-19 and is present in 83% of hospitalized patients [3, 27]. High D-dimer levels and lymphopenia are associated with mortality [30, 46].

Although procalcitonin level is normal at presentation; its level is possibly increased in patients admitted to the ICU [27, 26, 28]. Cardiac troponin I levels were found to be substantially high only in patients with severe COVID-19 in addition to low level of lymphocytes, high levels of LDH, and D-dimer in a meta-analysis evaluating 341 patients [103].

CONCLUSION

COVID-19 disease is a contagious and fatal infection that has spread all over the world in a short time. We have observed up to now that the infection is mostly asymptomatic; symptomatic and severe infection develops less frequently. The incubation period is 2-14 days with an average of 4-5 days. The most commonly seen complaints are fever, cough, myalgia, fatigue, diarrhea, and loss of taste and smell. Pneumonia is the most common sign of serious infection and severe infection is developed in approximately 15% of the patients with hypoxia, dyspnea, or diffuse pulmonary involvement. ARDS is the main complication in patients with severe disease and it might be observed a short while after the start of dyspnea. Many other complications including thromboembolic events, acute cardiac damage, and inflammatory complications have been reported. The risk of developing severe disease and mortality is high in elderly individuals and individuals with comorbidities. Laboratory parameters and imaging studies will be of guidance in the course of the disease. A good understanding of the clinical and laboratory findings of the COVID-19 disease will play a major role in the early diagnosis of the disease and the control of the outbreak.

ABSTRACT

The pandemic that emerged at the beginning of this year spread rapidly all over the world. The most effective way to combat such a large-scale epidemic is to quickly diagnose infected individuals and take necessary isolation measures. Although rapid antigen tests used in the first stage in the diagnosis of COVID-19, they have quickly left their places to molecular-based real-time PCR tests due to sensitivity problems. Antibody response based diagnosis can be problematic because those found can become detectable as early as 2 weeks after the onset of infection, which is not a suitable acquisition for the diagnosis of acute infection. In this article, applications and methods used for the diagnosis of COVID-19, will be discussed.

Keywords: SARS-CoV-2, COVID-19, real-time PCR, diagnosis

INTRODUCTION

At the end of 2019, a new type of pneumonia caused by a novel coronavirus emerged in the city of Wuhan, China. Then this virus has spread rapidly worldwide. The World Health Organization (WHO) named the disease Coronavirus Disease 2019 (COVID-19) and the virus called severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). SARS-CoV-2 infections can cause common symptoms of viral pneumonia, like cough, fever, dyspnea, and

* Corresponding Author's Email: femitabak@yahoo.com.

myalgia. These symptoms are not specific for COVID-19. Therefore, patient history (contact with a suspicious or confirmed case, travel, etc.) constitutes the starting point for the diagnosis of COVID-19. The diagnostic algorithm of COVID-19 initially includes epidemiological history, clinical signs, CT scan, blood count, and biochemistry test results. Following these routine tests, showing the viral genome by nucleic acid amplification techniques (NAT) (like real-time PCR) may prove the diagnosis. Besides NAT, detection of IgM/IgG responses by serological tests and viral antigens by point-of-care tests (POCT) may be helpful.

COMPUTED TOMOGRAPHY AND OTHER BIOCHEMICAL PROPERTIES

Computed tomography (CT) results may give information about the severity of SARS-CoV-2 infection and be used for rapid pre-diagnosis and prognosis prediction. Abnormal CT scans with bilateral patchy shadows or ground-glass opacity, bilateral pulmonary parenchymal involvement, and consolidative pulmonary opacities in the lungs found around 86% of the patients at the time of their hospital admission. Besides these findings no radiographic or CT abnormality was found in 3% of patients with severe disease and 18% of patients with mild disease also had no radiological sign. Nevertheless, there is a limitation in these early reports in regards to severity classification because the criteria were not well defined. However, these findings cannot be differentiated from other viral pneumonia, and in some different clinical situations, they have similar images. It should not be forgotten that it can be obtained [1-4].

The most common finding in hemogram is lymphopenia. It may occur in 70-83% of patients. Detoloration and persistence of lymphopenia combination with high levels of inflammatory cytokines, correlated with disease severity and mortality. Coagulopathy and disseminated intravascular coagulation related to other biomarkers like D-dimer and fibrinogen, procalcitonin, and troponin, also strongly correlated with clinical severity and mortality [4-6].

Sample Collection

The virus begins to spread in the upper respiratory tract 1-3 days before onset of the symptoms. Virus especially has high titers in the first week of the disease. The virus load in the upper respiratory tract decreases in the second week and it is found in greater amounts in the lower respiratory tract samples. For the diagnosis of COVID-19, upper respiratory samples are the most common samples, but sputum (who can produce sputum) or lower respiratory tract samples such as broncho alveolar lavage fluid (BAL), endotracheal aspirate can also be taken in patients. In the second week of the disease, lower respiratory tract samples can be preferred. Nasopharyngeal and oropharyngeal swab samples (alone or, preferably, in a combination of them) nasopharyngeal irrigation and nasal aspiration fluids are samples of upper airways. A healthcare professional can take these samples or the patient can give these samples to himself. Similar results reported both nasopharyngeal swabs and nasal swabs that the person obtains himself. Apart from this, more reproducible results can be

obtained, especially with saliva samples originating from the pharynx posterior wall. Because of a high risk of aerosol generation, infection control measures should be taken when collecting lower respiratory tract samples such as induced sputum, BAL, or endotracheal aspirates. In the first 14 days after the onset of the disease, the most reliable example to detect SARS-CoV-2 is nasopharyngeal swab after sputum and then throat swab. In addition, the virus begins to be excreted with feces, especially from the second week and continues to be excreted with feces for a long time. Since viral excretion in upper respiratory tract samples may be low or irregular, especially in advanced stages of the disease, stool samples can be useful for diagnosis. However, since the viral load varies according to the samples and the severity/period of the disease, the negative test result obtained with samples taken from the upper respiratory tract does not exclude the disease, and in case of clinical suspicion, the test should be repeated a second time or by taking a different sample that may have higher sensitivity [6-8]. Single nasopharyngeal swab samples are becoming more preferred because they have better tolerated by the patient and safer for the sampler.

Timing and technique of sample collection have grand effect on the sensitivity of molecular tests. Yang et al. found the highest positivity rates in the first 7 days and samples taken from seriously ill patients. They obtained the highest positivity rates in BAL samples (78.6-100%) in severe patients [9]. In another study conducted in China, the positivity rates were 93% for BAL, 72% for sputum, 63% for nasal swabs, 32% for pharynx swabs, and around 29% for feces [10]. In contrast, besides more frequent usage of oropharyngeal swabs, compared to nasopharyngeal swab samples, SARS-CoV2 RNA was detected in only 32% of oropharyngeal swabs, which is significantly lower than the detection rate (63%) of nasopharyngeal swab samples [6, 9, 10]. Sampling technique (depend on the experience of health care worker), timing, quantity, so many other factors such as where the sample is taken, the transport and storage of the sample, the performance of the molecular test used, and the severity of the disease can seriously affect the test results.

Molecular and Serological Methods

The widely used technology for SARS-CoV-2 is reverse transcription followed by real-time polymerase chain reaction (RT-PCR) technology. RT-PCR is currently used in many microbiology laboratories in a very wide range from detection and quantification of the single pathogen to syndromic approaches and panels for the diagnosis of different infectious agents [1, 7]. Following the emergence and rapid spread of SARS-CoV-2 in China, many organizations have published their diagnostic protocols and then different commercial companies have released RT-PCR test kits for diagnosis, and some of these have been pre-approved or approved by different organizations such as the FDA and WHO.

The first step in RT-PCR is the synthesis of complementary DNA (cDNA) from the RNA genome. Then, the cDNA is amplified and detected using unique primer and probe systems. The development process of these tests generally involves two main steps, (i) selection of suitable gene regions means the selection of conserved regions in known sequences and performing primer/probe design (ii) Optimization and validation of the developed test. In a study by Corman et al., viral genomes associated with SARS include the RdRP gene (RNA-linked RNA polymerase gene), open reading frame ORF1ab region, E gene (envelope protein

gene), and N gene (nucleocapsid protein gene) are reported as conserved regions, and these regions are still frequently used target regions for RT-PCR [5, 6, 8, 11]. Studies on these gene regions have also reported that both RdRP and E genes have high analytical sensitivity (3.6 and 3.9 copies per reaction) and the N gene has weaker analytical sensitivity (8.3 copies per reaction). At the same time, the reaction buffers used in the tests, sample collection, and nucleic acid extraction methods, the devices used for performing RT-PCR and detection can affect the test's performance [7, 8, 12]. In the United States, CDC recommends two nucleocapsid protein targets [N1 and N2], while WHO recommends an initial screening with the E gene followed by a confirmatory test using the RdRp gene for more sensitive and specific results. Since the viral genes have equal copy numbers, the test should be well optimized as the test performance is usually determined not by the target itself but by the reagent design. At least two molecular targets should be included in the analysis to prevent false positive or negative results from potential genetic alterations of SARS-CoV-2, as well as potential cross-reactions with other endemic coronaviruses [6]. However, the WHO should include single target test formats with high specificity, especially during the epidemic period.

It is developed and evaluated in molecular methods worldwide other than RT-PCR. These include loop-mediated isothermal amplification, multiplex isothermal amplification methods, followed by microarray detection and CRISPR/Cas systems [30]. Cas13-based SHERLOCK (specific high-sensitivity enzymatic reporter unlocking) platform, that tested for detection of ZIKA and Deng viruses in patient samples. This method could detect at concentrations as low as 1 copy per microliter. Currently, Zhang et al. have adopted this technology to detect SARS-CoV-2, and the test has received FDA pre-approval [13].

According to WHO, the urgent priority for COVID-19 diagnostic research is the development of nucleic acid and protein tests and providing the opportunity to test at the bedside of patients (point of care tests, POC). The longer-term priority is to integrate these tests into multiple panels, as the leading multi-parametric respiratory pathogens panel manufacturers are adding SARS-CoV-2 to their panels. To improve surveillance efforts, serological tests using proteins are needed in addition to nucleic acid tests. These tests, unlike nucleic acid tests, have post-recovery detection advantages. This allows clinicians to monitor both sick and recovered patients, providing a better estimate of total SARSCoV-2 infections. POC tests are cost-effective devices used to diagnose patients outside of central facilities. These can be employed in areas such as community centers to reduce the burden on clinical laboratories [8].

Although RT-qPCR is specific for the diagnosis of COVID-19, false negativities cannot be ignored. The sensitivity of RT-PCR was found around 89% in a meta-analysis [14]. Since the sensitivity changes depending on the samples, their sensitivity in practice is even lower. Because of mild or asymptomatic cases with infection, the number of COVID-19 infections reported around the world so far does not reflect the actual infected people. For example, asymptomatic cases were reported to be 17.9% in the Diamond Princess ship study. All of these findings point to be considered in preventing the spread of the disease, as asymptomatic individuals constitute a serious source of transmission [8]. In this regard, the deficiencies of nucleic acid detection and CT scans for the diagnosis of COVID-19 and the fact that they are more applicable in central institutions. Considering that, there is a need for test formats that can work with samples that can be taken quickly and easily in the field. Immunologically based tests that can detect antigens or antibodies in cases where no results obtained with PCR tests may work in practice.

For the rapid detection of SARS-CoV-2 antigens or antibodies, some serological tests have been developed, and some of them have been approved by many institutions. Many different commercial companies develop serological tests for detection of SARS-CoV-2 infection in lateral flow tests, automated chemiluminescence immunoassay systems (CLIA), ELISA, and other formats. Although antibodies reach the detectable level from the seventh day of the disease during COVID-19, generally IgM responses can be detectable in the second week and IgG responses start from the 3rd week safely. Antibody responses can also be affected by several factors such as disease severity and host immune status. Although IgM responses remain positive for a shorter time, IgG positivity may persist for a long time. The level and duration of protection of antibody responses that develop after SARS-2 virus infections are not yet known. Its protection is estimated not to be very long (longer than 6 months). It is attractive that rapid antigen tests will theoretically allow low-cost and rapid detection of SARS-CoV2, but as with influenza (Flu) viruses, their sensitivity will be lower than molecular tests. The sensitivity of an antigen test approved by the FDA is 80%. Especially with the development of monoclonal antibodies, more and more sensitive antigen tests are being developed [6, 15]. Considering the variability of viral loads and sample diversity in COVID-19 patients, the problem of sensitivity of antigen tests will be better understood. Antibody tests that examine the host's response to the agent, on the other hand, maybe more useful in showing the previous infection. They can also be used as additional tests in confirming COVID-19 infection; However, in a situation where the prevalence is low, the false positivity rates of these tests will be very high despite their high specificity (for example, if the seroprevalence in the population is 1%, the probability of antibody positivity obtained with a specificity of 99% will remain around 50%). Therefore, it is recommended that they be used carefully, considering the limitations mentioned in auxiliary tests and seroepidemiological studies. The use of antibody tests for purposes such as investigating the presence of protective antibodies in individuals should be avoided. Previously, this type of serological testing has played an important role in the epidemiology of SARS and other coronavirus outbreaks. Rapid lateral flow tests that can detect both IgM and IgG antibodies will undoubtedly play an important role in COVID-19. However, there are specificity problems in IgM responses and the development of specific IgG response takes time. In this regard, serology tests do not seem likely to play a role in active case management, apart from tasks such as diagnosing/confirming late COVID-19 cases or determining individual immunity [1, 6, 8]. Serological tests can be used as an IVD test to complement existing RT-PCR tests, this can also lead to a much better diagnosis of COVID-19 and provide additional information about the immune status of suspected cases. However, the clinical accuracy of rapid tests must be rigorously evaluated before they can be authorized for mass screening of COVID19. Recent reports from many European countries suggest that most rapid tests for COVID-19 sourced from China did not show good analytical performance and did not work in more than 70% of COVID-19 cases. Besides, due to the late development of IgM and IgG responses, there is a need to include other biomarkers of the early stage of SARS-CoV-2 infection to develop practical COVID-19 rapid tests [5].

Although its use in the diagnosis of SARS-CoV-2 is limited due to its high cost, next-generation DNA sequence analysis is used especially for understanding and monitoring viral evolution and for genoepidemiological studies. At the same time, the US Food and Drug Administration granted Emergency Use Authorization (EUA) for Illumina's next-generation sequencing (NGS) test for COVID-19, in June. This is the first such authorization for an NGS

diagnostic. The testing yield was reported as 3,000 tests of nasopharyngeal or oropharyngeal samples with a 24-hour turnaround. The detection performance was reported at least 1,000 copies of the viral genome per milliliter and displays 98% sensitivity and 97% specificity by the company literature [5, 6, 8, 16, 17].

Chapter 456

TREATMENT OPTIONS FOR COVID-19 PATIENTS

Hakan Yavuzer^{1,*}, MD and Pınar Arman¹, MD

¹Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty,
Department of Internal Medicine, Division of Geriatrics, Istanbul, Turkey

ABSTRACT

COVID-19 disease was first defined in December 2019, and its causative agent was determined as SARS-COV-2 in January 2020.

There is no specific treatment for this infection that affects more than one organ system, especially the pulmonary system. Many medical treatments have been tried until today, and studies on their efficacy and safety have been published.

Anti-malarial drugs; anti-retrovirals, ribavirin, remdesivir, favipiravir, and other antiviral agents; corticosteroids; anti-cytokines and immunomodulatory agents; immunoglobulins are listed among the drugs evaluated. The mechanism of action, pharmacokinetic and pharmacodynamic properties, and side effects of each drug group are different. Medical treatment should be individualized considering these differences.

Keywords: COVID-19 treatment, chloroquine, ribavirin, remdesivir, favipiravir, corticosteroids

INTRODUCTION

Coronavirus-19 disease (COVID-19) was first reported in the Wuhan province of China in December 2019. Then, it was declared as a pandemic threatening the whole world by WHO on March 11, 2020. The causative agent, SARS-COV-2, belongs to the beta-coronaviridae family and has a single-stranded RNA structure. SARS-COV-2 encodes the S protein that binds human angiotensin-converting enzyme 2 (ACE2), thus membrane fusion occurs and the virus is allowed to enter the cell [1, 2]. Once inside the cell, SARS-COV-2,

* Corresponding Author's Email: drhakanyavuzer@gmail.com.

like other coronaviruses, controls the cell's synthesis mechanisms for the synthesis of viral proteins and viral replication [3].

Once the virus enters the human body, it usually induces a range of host responses such as autophagy, apoptosis, stress response, and innate immunity [4].

Some of these immune responses can be protective for patients, while others can be harmful. The protective immune response allows the patients to go through the disease with asymptomatic or mild symptoms. It has been found that approximately 80% of people infected with SARS-COV-2 developed a protective immune response. Providing interferon synthesis by stimulating the natural immune system including natural killer cells and T cells plays an important role in the formation of a protective immune response [5, 6].

In elderly, immunosuppressed patients or individuals with diabetes, hypertension, obesity, chronic obstructive pulmonary disease (COPD), pulmonary fibrosis, asthma and interstitial diseases, COVID-19 progresses with more severe respiratory symptoms and acute respiratory distress syndrome (ARDS), and may even result in death. SARS-CoV and MERS-CoV, which are members of the coronavirus family, have mechanisms that reduce or delay interferon production; this leads to increased inflammatory response and exacerbation of lung damage [7, 8]. Cytokine storm, known as overproduction of inflammatory cytokines, is associated with increased disease severity and poor prognosis [4, 9].

An increase in cytokine production, indicative of cytokine storm, has been detected in the bronchoalveolar lavage fluid and peripheral mononuclear blood cells of COVID-19 patients [10]. Besides the lungs, SARS-Cov-2 also affects other organs, especially the heart and brain. There is no specific drug or vaccine for SARS-Cov-2 yet. Therefore, the treatment of severe cases is challenging. Until specific drugs or vaccines are found, it is recommended to use other drug groups that have been shown to be effective in studies.

CURRENT DRUGS IN THE TREATMENT OF COVID-19

Since there is no specific drug for treatment; early diagnosis, isolation of patients and rapid provision of supportive treatments are life-saving. Treatment of COVID-19 patients is based on the reassessment of existing medications and, primarily, improvement of symptoms. Since ARDS and secondary bacterial infections frequently develop in patients; antibacterial, anti-inflammatory, and immunomodulatory drugs take their place in the treatment in addition to antiviral agents.

ANTIMALARIAL AGENTS

Chloroquine and hydroxychloroquine have been developed for the treatment of malaria and have proven effective in the treatment of chronic inflammatory diseases such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). By inhibiting the glycosylation of host receptors, proteolysis and endosomal acidification prevent viruses from entering the cell. In addition, they decrease cytokine production and regulate immunomodulation by inhibiting autophagy and lysosomal activity. In a multi-center,

randomized study, it was shown that the anti-inflammatory effect of hydroxychloroquine may be beneficial in COVID-19 patients [11].

However, hydroxychloroquine added to standard therapy does not increase the virus response; it decreases inflammation and the severity of lymphopenia and accelerates the regression of symptoms. It is thought that the patient group benefitting the most from hydroxychloroquine is the patients with high CRP and lymphopenia.

A meta-analysis of 42 studies showed that hydroxychloroquine was not associated with overall mortality [11]. In the same meta-analysis, it was shown that the fever response developed more rapidly in patients using hydroxychloroquine.

For the treatment of COVID-19, the chloroquine dose is 500mg orally, once or twice a day [12]. However, there are very few data proving the safety and efficacy of these doses. The recommended dose of hydroxychloroquine is 2 x 200mg per day after a 2 x 400mg loading dose [13].

Antimalarial drugs are generally well tolerated. QT prolongation, hypoglycemia, neuropsychiatric effects, and retinopathy are rare (10%) but serious side effects of hydroxychloroquine. QT prolongation; especially in patients with advanced age, female patients, individuals with a history of heart disease, hypokalemia or kidney and liver failure, patients using diuretics, such as furosemide and thiazide, and other drugs that prolong the QT interval is more frequently observed. ECG should be taken before treatment to evaluate and follow-up on the QT prolongation. No significant side effects of chloroquine used at the indicated doses and duration for the treatment of COVID-19 have been reported. These drugs are safe during pregnancy.

In a review evaluating 12 studies, it was found that chloroquine and hydroxychloroquine used during pregnancy do not cause ocular toxicity in the newborn [14].

ANTIVIRAL AGENTS

Favipiravir

Favipiravir is used in the treatment of avian influenza or influenza that is resistant to neuraminidase inhibitors. It is a guanine analog, its antiviral activity is reduced by competition in the presence of purine nucleosides. Favipiravir is taken up into the infected cell by endocytosis and transforms into the active form by phosphoribosylation and phosphorylation. It targets the catalytic part of the RNA-dependent RNA polymerase, thus, it shows antiviral activity by disrupting the nucleotide sequence during viral RNA replication. It has been used in the treatment of RNA virus infections such as influenza, Ebola, and norovirus [15]. There are in- vitro and human studies which is used experimentally in the treatment of SARS-CoV-2. In a randomized controlled study comparing favipiravir and umifenovir, it was reported that the recovery rate was higher (71.4%) and the recovery time of fever and cough symptoms was shorter in the favipiravir group [16]. In another study, significant radiological improvement, faster reduction in viral load, and fewer side effects were observed in patients who received favipiravir compared to the control group [17].

The dose of favipiravir varies according to the viral agent detected. For example, in influenza treatment, lower doses are sufficient compared to ebola and SARS-Cov-2 treatment.

The high dose range is also considered for the treatment of COVID-19 [18]. After a loading dose of 2400-3000 mg given every 12 hours on the first day, a maintenance dose of 2 x 1200-1800 mg/day is recommended. Its side effects are mild and can be treated. An increase in liver enzymes, hyperuricemia, psychiatric symptoms, and gastrointestinal side effects are seen.

Lopinavir/Ritonavir

Lopinavir is a protease inhibitor with a high affinity for HIV-1 protease. It is used in combination with ritonavir to increase the oral bioavailability and effectiveness of lopinavir. Since SARS-CoV-2 is an RNA virus like HIV, lopinavir/ritonavir has been used in the treatment of this infection. It has also been recommended in the treatment of COVID-19 due to the existence of studies that have found that it reduces the mortality in patients infected with SARS-CoV-1 [19]. Preliminary studies are showing increased viral clearance in COVID-19 patients treated with lopinavir/ritonavir [20]. However, a meta-analysis showed that this combination did not reduce the time of hospitalization and mortality compared to the control group [21]. The dose of lopinavir/ritonavir in the treatment of COVID-19 is 400mg/100mg twice a day. The duration of treatment is 14 days. Since there are prominent drug-drug reactions and side effects, the drugs used by the patients should be reviewed before the treatment and their side effects should be closely monitored. The most common side effects are nausea, vomiting, and hepatotoxicity. Approximately 50% of patients using lopinavir/ritonavir experience side effects; the rate of quitting the drug due to these side effects is 14% [22].

Ribavirin

Ribavirin is a guanine analog that inhibits RNA-dependent RNA polymerase. Although its effectiveness against other coronaviruses is known, its in-vitro activity against SARS-CoV2 is limited and requires higher doses. It is not recommended in first-line therapy. The efficacy of ribavirin has mostly been evaluated in combination therapy. In a multicentre, prospective, open-label, randomized controlled trial, it was shown that lopinavir and ribavirin combination therapy resulted in better compliance, faster viral clearance, and shorter hospital stay compared to lopinavir/ritonavir and ribavirin combination or ribavirin monotherapy [23]. In a systematic review that included 30 studies evaluating the effectiveness of ribavirin in COVID-19, inadequate results were obtained in 26 studies; severe hematological and hepatic side effects were reported in 4 studies [24]. The recommended dose of ribavirin is 1000-1500mg per day [25]. It is administered intravenously, the maximum duration of treatment is 10 days [25]. Ribavirin commonly has haematologic and hepatic side effects. Its hematological side effects are dose-dependent. It has been reported that hemolytic anemia developed in 60% of the patients and increased transaminases in 75% of the patients who received high-dose ribavirin for the treatment of SARS [24]. Also, ribavirin is teratogenic and should not be used during pregnancy [26].

Remdesivir

Remdesivir is the first antiviral drug developed for Ebola virus treatment [27]. It is an adenosine analog and a prodrug that disrupts viral RNA synthesis. In addition to the Ebola virus, it is effective against different virus families including Filoviridae, Paramyxoviridae, Pneumoviridae, and Orthocoronavirina. In animal studies evaluating its efficacy on SARS-CoV-2, remdesivir has been observed to reduce viral load, rate of disease progression, and improve pulmonary function [28]. A randomized, double-blind, placebo-controlled trial demonstrated that the duration of clinical recovery was similar in the remdesivir and control groups [29]. A limitation of this study was that lopinavir/ritonavir, corticosteroid, and/or interferon could be used in both remdesivir and control groups. There are also studies proving the opposite. In another randomized controlled study comparing 538 patients treated with remdesivir and 521 patients treated with placebo, the mean recovery time in the remdesivir group was four days shorter than the control group [30]. Remdesivir is the first antiviral agent approved recently by the FDA for the treatment of COVID-19.

For the currently studied therapeutic dose of remdesivir; after a single loading dose of 200 mg on the first day, the maintenance dose is 100mg once a day. It is administered as an IV infusion. There are no clear data on the duration of treatment, and no significant difference was found between the two treatment durations in the Phase III study evaluating the 5 and 10-day treatment durations (NCT04292899). The most common side effects are constipation, hypokalemia, anemia, thrombocytopenia, and increased bilirubin levels. It is not recommended for use in patients with liver and kidney failure.

ANTIBACTERIAL AGENTS

Azithromycin

In vitro efficacy of azithromycin, an antibiotic from the macrolide group, against the Ebola virus has been demonstrated [31]. It is also effective in preventing severe pulmonary infections in patients with viral infections. In a study evaluating the combined regimen with hydroxychloroquine in 20 COVID-19 patients, azithromycin was shown to increase the efficacy of hydroxychloroquine [32]. However, the risk of QT prolongation should be considered in combination with hydroxychloroquine.

Teicoplanin and Other Glycopeptides

Another antibacterial agent that stands out in the treatment of coronavirus infections is teicoplanin. It has been shown in vitro that teicoplanin prevents the entry of other coronaviruses such as Ebola, MERS, and SARS into the cell [33]. However, there is no study showing its effectiveness on SARS-CoV-2.

IMMUNOMODULATOR AND IMMUNOSUPPRESSIVE AGENTS

Interleukin-6 Inhibitors

Tocilizumab is a human IL-6 receptor antagonist; it is used in the treatment of RA and cytokine release syndrome (CRS). It is observed that IL-2 receptor, IL-6, IL-8, IL-10, and TNF-alpha levels are increased in COVID-19 patients with cytokine storm. Increased cytokine release is associated with increased disease symptoms. Since IL-6 may play an important role in stimulating the excessive inflammatory response in the lungs with COVID-19 involvement, tocilizumab is thought to be effective in the treatment of this infectious disease. In a multi-center study, it was observed that 75% of the patients with severe COVID-19 disease experienced an improvement in fever and a decrease in oxygen demand [34]. In the same study, regression was found in CT findings and improvement was seen in CRP increase and lymphopenia [34]. The mortality rate was also significantly lower in the tocilizumab group compared to the control group. However, the most important disadvantage of this study is that it was not randomized and double-blind.

The dose of tocilizumab with demonstrated efficacy in the treatment of COVID-19 is a single 400mg IV infusion [35]. If fever persists within 12 hours after the first dose, a second dose may be administered. Its known side effects include increased risk of bacterial infection, gastrointestinal perforations, infusion-related reactions such as hypertension, headache, skin reactions, anaphylaxis, thrombocytopenia, increased liver enzymes, and hyperlipidemia [36]. The same side effects are seen in the treatment of COVID-19 [37]. Sarilumab is another human monoclonal IL-6 receptor blocker. The multi-center, double-blind, phase II/III study (NCT04315298) evaluating the effectiveness of this molecule, which has been developed for the treatment of RA, in COVID-19 treatment has not yet been concluded. Nevertheless, it showed that it may be more effective to reduce CRP than placebo. However, no data is showing the benefit of sarilumab in severe disease. It is not recommended for the treatment of COVID-19 for now due to insufficient efficacy and safety studies.

IL-1 Receptor Antagonists

Anakinra is a recombinant human IL-1 receptor antagonist and is used in the treatment of RA. Studies are showing that it is effective in macrophage activation syndrome (MAS) in which severe cytokine storm is observed [38]. Therefore, it is thought that anakinra may prevent symptoms of COVID-19 related cytokine release syndrome. Use of anakinra improved survival in patients with sepsis in a phase III, randomized controlled trial [39]. Currently, no randomised controlled studies are evaluating the efficacy and safety of its use in the treatment of COVID-19. In case series and cohort studies published so far, anakinra has been shown to improve clinical and laboratory markers, reduce the need for mechanical ventilation and mortality rates [40, 41].

Janus Kinase Inhibitors

It is suggested that Janus kinase (JAK) inhibitors may be effective in the treatment of CRS in severe COVID-19 disease by inhibiting the JAK-signal converting activator (JAK-STAT) pathway. Ruxolitinib is a potent and selective oral JAK1 and JAK2 protein kinase inhibitor. It is indicated for intermediate and high-risk myelofibrosis, polycythemia vera, steroid-resistant graft versus host disease. There is not yet sufficient data regarding the use of ruxolitinib and other JAK inhibitors in the treatment of COVID-19. In ongoing phase III studies (RUXOCOVID, RUXCOVID-DEVENT), the efficacy of ruxolitinib in the treatment of COVID-19 associated CRS and ARDS patients in need of mechanical ventilation is evaluated.

Anti-Tumor Necrosis Factor- α

Tumor necrosis factor- α (TNF α) plays a role in all acute inflammations induced by acute stress and inflammation. TNF α is a molecule produced mainly in macrophages, monocytes, B cells, and other tissues. With the activation of TNF α , IL-1 and IL-6 begin to be produced. Plasma and tissue TNF levels were found to be high in COVID-19 patients [42]. Anti-TNF α agents such as adalimumab and infliximab are indicated for the treatment of inflammatory and autoimmune diseases such as RA, inflammatory bowel disease, and ankylosing spondylitis. Experimental studies are showing the effectiveness of anti-TNF α in the treatment of viral pneumonia [43].

The ability of a single dose of anti-TNF α to significantly lower blood TNF α levels suggests that it may be useful in the treatment of COVID-19 [44]. However, it should be considered that anti-TNF α therapy causes an increased risk of bacterial and fungal infections [44].

Intravenous Immunoglobulin

Intravenous immunoglobulin (IVIG) includes Ig G subtypes obtained by pooling from human plasma. It was used to provide immunity in the treatment of SARS, but thromboembolic complications were reported in some cases and the expected benefit could not be obtained [45, 46]. There may be several mechanisms that are effective in the therapeutic benefit of IVIG. IVIG can inhibit the function of many innate immune cells and neutralize active complement components.

It can also affect the acquired immune response by regulating the functions of B and plasma cells, regulator T and T helper cells, and inhibiting inflammatory cytokines.

In addition, it can stimulate the anti-inflammatory response by binding to antiviral antibodies and pro-inflammatory cytokines [47]. In a retrospective study of 58 patients with severe COVID-19 pneumonia, it was observed that IVIG treatment administered within 48 hours after the appearance of clinical findings significantly reduced 28-day mortality compared to the administration of the treatment 48 hours later (23.3%; 57.1%, $p = 0.009$) [48].

In contrast, another retrospective study involving 325 patients reported that IVIG treatment given to severe COVID-19 patients had no positive effect on 28-day or 60-day mortality [49]. Since current IVIGs do not contain antibodies against SARS-CoV-2, IVIG treatment is recommended in COVID-19 treatment guidelines of the National Institute of Health and Surviving Sepsis Campaign [50, 51].

Interferons

Interferons (IFNs) are cytokines that play a key role in reducing viral replication and regulating the immune response against viral infection. The effectiveness of IFN treatment against MERS-CoV and SARS-CoV has been studied. Due to their nonspecific antiviral effects, the effectiveness of combination therapies with other agents has generally been evaluated [52]. In a multi-center, prospective, open-label, randomized, phase II study evaluating 127 patients with COVID-19 disease, it is suggested that the duration of weaning from the mechanical ventilator, hospital stay, and viral carriage time were shorter with lopinavir/ritonavir, ribavirin, and IFN β -1b combination therapy compared to monotherapies [23]. Clinical studies evaluating the effectiveness of nebular and subcutaneous forms of interferons in the treatment of COVID-19 (NCT04293887, NCT04350281) continues.

Corticosteroids

Corticosteroids have taken their place in the treatment of many diseases such as asthma and other allergic diseases, autoimmune diseases, septic shock, and cancer. On the one hand, they suppress inflammation, on the other hand, they may predispose to infections by causing immunosuppression. It is a class of drugs that have been tried in treatment since the beginning of the COVID-19 pandemic. WHO and CDC did not recommend corticosteroids in the treatment of COVID-19 if there are no comorbidities such as asthma, COPD, and sepsis since their efficacy on SARS and MERS could not be determined and their side effects could be fatal. However, many studies have shown the opposite. Treatment with steroids has been shown to reduce the risk of death in COVID-19 patients who develop ARDS. While the mortality rate is 46% in patients receiving steroid treatment, it is 61.8% in patients who do not [53]. Similarly, the randomized, controlled RECOVERY study showed that dexamethasone reduced the mortality rate in 1/5 of the patients who needed noninvasive oxygen treatment, and in 1/3 of the patients who needed mechanical ventilation [54]. In addition, dexamethasone reduced the length of hospital stay and the need for mechanical ventilation [54].

Important side effects of corticosteroids are avascular necrosis, psychosis, gastrointestinal effects, and diabetes. In the aforementioned RECOVERY study, no side effects were reported in patients given dexamethasone compared to the control group [54]. As a result of the increase in studies supporting the efficacy and safety of corticosteroids, it has been emphasized in the treatment guidelines that short-term (<8 days) and low-dose (0.5 - 1mg/kg/day methylprednisolone and its equivalent) steroid treatment can be administered [55].

OTHER PHARMACOLOGIC THERAPIES

Convalescent Plasma Therapy

Serum obtained from people who have recovered from an infectious disease, called convalescent plasma, has been used for a long time in the treatment of infectious diseases. Antibodies in plasma show their therapeutic effects by more than one mechanism. The antibodies can act by binding directly to the agent. In a second mechanism, antibodies produce their therapeutic effect by stimulating complement activation, phagocytosis, and antibody-mediated cytotoxicity. Plasma therapy has been used effectively and reliably in the SARS, MERS, and H1N1 pandemics for the last 20 years [56-58]. Since SARS-CoV-2 has similar virological and clinical properties with SARS-CoV-1 and MERS, it is thought that plasma therapy may also be effective in the treatment of this viral infection [59]. In the first studies conducted with COVID-19 patients, it was reported that ARDS symptoms regressed, the duration of mechanical ventilation was shortened, fever decreased, and viral clearance increased [60, 61].

However, these studies are small-scale and single-center studies. Plasma therapy is generally well tolerated; Common side effects are transfusion-related skin reactions, hypervolemia, and lung damage. Recently, an FDA-supported, national, multi-center, open-label EAP study was conducted in 5,000 inpatients with high-risk and very severe COVID-19 findings [62]. Less than 1% of the patients developed serious side effects such as transfusion-related hypervolemia, transfusion-associated lung injury (TRALI), and severe allergic reaction.

On the other hand, a multi-center, randomized controlled study evaluating the efficacy and safety of plasma treatment in 103 COVID-19 patients with severe or life-threatening diseases conducted in China; found recovery time, mortality rate, and length of stay to be similar to the control group [63].

In the same study, no major side effects were reported [63]. The recommended plasma dose for the treatment of COVID-19 varies depending on the neutralizing antibody level and is one or two infusions.

Renin-Angiotensin-Aldosterone System (RAAS) Inhibitors

Besides the protective effects of RAAS inhibitors on the cardiovascular system, they also have anti-inflammatory and immunomodulatory effects.

ACE2 is secreted from all epithelial cells, including lung epithelial cells. ACE2 receptors are the entry point to the host cell for SARS-CoV-2 [64]. The virus binds to ACE2 and inhibits it and the level of angiotensin 2 increases. It has been hypothesized that ACEIs and ARBs exacerbate clinical findings by increasing the number of ACE2 receptors that will allow SARS-CoV2 to bind. However, this hypothesis has not been proven by human studies.

In a large-scale, observational study, SARS-CoV-2 positivity was found in patients using ACEI/ARB at a similar rate to patients not using it [65]. In addition, disease severity was similar in both patient groups [65]. In a case-control study conducted with 6272 COVID-19 patients, it was shown that the use of ACEI/ARB was not associated with the risk of COVID-

19 infection, the severity of clinical findings, or the course of infection [66]. Based on these and similar studies, discontinuation of ACEIs/ARBs in the treatment of patients is not recommended unless there is hemodynamic impairment.

Statins

Statins play an important role in the treatment of cardiovascular diseases. They may be useful in the treatment of COVID-19 due to their anti-inflammatory effects and protective effects on the innate immune system [67].

In a multi-center retrospective study aimed at determining the prevalence of myocardial damage in COVID-19 patients, statins have been reported to increase survival in these patients [68]. In another retrospective study, it has been shown that statin use is notably associated with asymptomatic disease [69].

In the same study, the severe disease was observed in 19% of those using statins, while it was observed in 25% of those who did not; but this was not statistically significant [69]. In patients diagnosed with COVID-19, if treatment with a statin is indicated, the drug should be started or continued.

CONCLUSION

Since the beginning of the SARS-CoV2 pandemic, many different drug groups have been tried for the treatment. However, no specific agent has been developed so far. Drugs act by blocking virus entry into host cells, inhibiting viral replication, and suppressing excessive inflammation. The side effects of the drugs also differ. Treatment protocols should be individualized, taking into account factors such as the patients' clinical conditions, accompanying diseases, and other medications. Treatment protocols will change as the efficacy and safety studies of each drug group are completed.

Chapter 457

INTENSIVE CARE MANAGEMENT OF COVID-19 PATIENTS

Olcay Dilken, MD and Yalim Dikmen*, MD

Istanbul University-Cerrahpasa, Cerrahpasa Medical School,
Department of Anaesthesiology and Reanimation, Istanbul, Turkey

ABSTRACT

COVID-19 has affected millions of patients and healthcare workers in an unprecedented way. The pandemic took clinicians and hospitals by surprise. Intensive care units should be modified to handle the patient surge. There are few remedies to decrease the burden imposed on the healthcare system. These include management of acute respiratory failure, thrombotic events, cytokine modulating therapies. Only dexamethasone and prone positioning seem to have beneficial effects on oxygenation and need for mechanical ventilation. Nevertheless, tailoring the therapy for specific needs of the patient can decrease adverse effects. In this chapter, we review the current knowledge in the management of the critically ill COVID-19 patients as of September 2020.

Keywords: COVID-19, pneumonia, ARDS, prone position, thrombosis, mechanical ventilation

INTRODUCTION

Since December 2019, a novel coronavirus, named “Severe Acute Respiratory Syndrome Coronavirus 2” (SARS-CoV-2), affected millions of lives. The illness it causes was termed Coronavirus Disease 2019 (COVID-19). It reached pandemic status by March 2020 and has been putting enormous strain on Intensive Care Units (ICUs) worldwide, both by overwhelming limited ICU capacity and lack of effective treatment options. [1] This new

* Corresponding Author’s Email: ydikmen@istanbul.edu.tr.

disease showed an unpredictable clinical course, especially in critically ill patients leading to high intensive care mortality exceeding 50 % [1, 2].

ICU ORGANIZATION DURING COVID-19 SURGE

In a recent retrospective cohort of 83,619 patients, mean ICU admission among hospitalized patients with COVID-19 pneumonia was 20.1% [range 4.6-32%]. 48.8% of these patients required invasive mechanical ventilation for a mean of 7.8 days or longer [3]. One of the early studies from the Lombardy region in Italy showed that the patients were generally admitted to the intensive care 10 days after the symptom onset, had a median 12 days length of stay. Main risk factors associated with mortality were advanced age, male sex, comorbidities like chronic obstructive respiratory failure and diabetes mellitus, low PaO₂/FiO₂ ratio and need for high positive end-expiratory pressure (PEEP)[1].

There are vast differences in ICU capacity not only among countries but also on the regional level. Thus, it would be impossible to assess the adequacy of all ICU beds for any given pandemic. However, measures to support the ICUs in case of overwhelmed capacity should be taken beforehand. The consequences of not doing so are possible delays in treatment, which is directly associated with mortality[4].

In contrast to a laypersons' belief, ICUs are driven by specialized physicians, skilled nurses, and other healthcare workers, not by medical devices. Insufficiently trained staff may jeopardize patient care. An intensivist-to-patient ratio lower than 1/15 was associated with increased ICU length of stay [5]. The nurse-to-patient ratio is another parameter that assures patient safety. During the peak patient surge in our ICU, we addressed this issue with former ICU nurses and anaesthesiologists to triple our capacity. It should be underlined that unskilled or too much staff may cause problems rather than benefit[6].

Lack of mechanical ventilators led to excess mortality in Northern Italy during early 2020. Strategies should be developed to overcome the shortage. High-flow nasal oxygen (HFNO) and non-invasive ventilation (NIV) can be employed to reduce the need for intubation. However, when intubated, a full-featured ventilator is necessary to manage a COVID-19 patient as opposed to basic volume control resuscitation devices or flow generators[3]. If a shortage occurs, alternative devices such as transport ventilators, anesthesia ventilators can be employed as a last resort. Concomitant use of a single ventilator on multiple patients is nowhere near logical or physiological and never advised.

Although healthcare staff and mechanical ventilators seem to bore the brunt of the surge, many supplies and resources are necessary for an intubated ICU patient. An exhaustive list can be found in [3]. To better deploy sources during a crisis, postponing all elective and medical procedures, providing refresher courses to former critical care staff and transfer of essential healthcare workers from less strained regions should be considered. However, a treatment that has been administered only in an ICU setting before the crisis (such as non-invasive ventilation), should never be transferred to another facility without sufficient experience (like wards).

COVID-19 RELATED ACUTE RESPIRATORY FAILURE

Physicians have been encountering an unprecedented number of acute hypoxemic respiratory failure and ARDS due to COVID-19 for the past 10 months. Acute Respiratory Distress Syndrome (ARDS) occurs in 20-41% of severe COVID-19 patients and they exceedingly require some form of ventilatory support. Non-invasive ventilatory support can be appropriate. However, the failure rate is high and, in some patients, invasive ventilation is inevitable [7].

ARDS is a heterogeneous syndrome that can present as in strikingly different types. Unfortunately, this fact seemed to be forgotten during the start of the pandemic, and patients were termed based on observations. “Happy hypoxemia, Type L and Type H (or high and low elastance), cytokine storm” were proposed in a desperate attempt to clarify a previously unknown disease. Although different treatments for different ARDS types were proposed, emerging evidence shows that respiratory system mechanics of patients with ARDS (with or without COVID-19) are similar [8]. Evidence-based management of “conventional” ARDS includes conservative fluid strategy, early and proper antibiotics for possible bacterial pneumonia, consideration for early invasive ventilation, lung-protective ventilation, use of prone positioning, and considering extracorporeal membrane oxygenation (ECMO) [9]. Additionally, three recent studies proved dexamethasone to be effective in severe COVID-19 patients (see below). Lung protective ventilation, even in patients with relatively conserved lung compliance, can be beneficial [10]. Also, lung-protective ventilation decreases progression to more severe ARDS and pulmonary complications [11]. Furthermore, permissive hypercapnia is mostly well tolerated. However, the acceptable level of carbon dioxide may significantly differ between patients. Thus, before advancing to more liberal tidal volume ventilation, other causes for the hypercarbia should be addressed. PEEP titration remains necessary and complicated for each patient as it possesses the risk of reducing oxygen delivery if the underlying cause leading to hypoxemia is vascular derangement (i.e., pulmonary emboli).

Prone positioning, both in non-intubated and intubated patients, improves oxygenation due to better ventilation-perfusion matching. Prone positioning the patient relieves the dorsal compression of the alveoli by the weight of mediastinum and intraabdominal organs. Subsequently, recruitment occurs and more alveoli are available for gas exchange. Also, continuous alveolar recruitment and derecruitment decrease within tidal volumes [7, 12]. It remains the mainstay of the management of ARDS patients. It can also be performed in awake patients with non-invasive forms of ventilatory support. In a prospective cohort of 56 patients, prone positioning was feasible in 84%. These patients maintained a prone position for at least 3 hours. Oxygenation improved remarkably after prone positioning. However, oxygenation could not be maintained in half of the patients when supine positioning was reinitiated. Early initiation of prone positioning after hospital admission (i.e., 2.7 days vs 4.6 days) was associated with retaining oxygenation [7].

One of the most crucial problems in the management of COVID-19 related ARDS is the timing of intubation and whether to commence invasive mechanical ventilation early. Unfortunately, anecdotal reports and expert opinions are insufficient to answer these questions. In one retrospective study, which analyzed patients from the Wuhan district in China, it was suggested that early intubation and invasive mechanical ventilation were more

effective in reducing mortality [13]. However, in this study, invasive mechanical ventilation was initiated only after failed non-invasive respiratory support, and this is hard to consider as an early intervention. Another retrospective multicenter study involving 48 ARDS patients from China had a better methodology, which compared the outcome in patients who were intubated at the time when they fulfilled the ARDS criteria versus the patients intubated after failed noninvasive support [14]. In this study, no difference in mortality was observed in early or late intubation groups. Additionally, 8 patients in the late group never received intubation. A recent survey replied by 1132 ICU physicians from 85 countries showed great heterogeneity in treatment practices regarding admission time, initial oxygenation strategies, ventilator management, etc. In this survey, only 8% of the respondents opted for early intubation in a hypoxaemic patient despite conventional oxygen treatment. Half of the respondents indicated 4 hours of observation before switching to invasive ventilation [15].

Corticosteroids, such as dexamethasone, can reduce the duration of mechanical ventilation and mortality in ARDS patients. In a multicentre randomized controlled trial on 277 patients with (non-COVID) ARDS, patients receiving dexamethasone had more ventilator-free days (12 vs 7, between group difference 4.8 days (95CI% 2,57 to 7,03). There was a slight increase in newly acquired infections and hyperglycemia [16]. The first major trial to show benefit in COVID-19 patients was the recovery trial that enrolled 6425 patients [17]. Of these, 2104 patients received 6 mg/day dexamethasone for 10 days. The mortality was significantly reduced in patients receiving respiratory support (including supplemental oxygen). However, there was no mortality difference among patients that did not receive respiratory support. Three subsequent RCTs were published in ICU settings to address the use of corticosteroids. In the REMAP-CAP trial, hydrocortisone was likely to be superior to no hydrocortisone (93% probability) [18]. CoDEX trial enrolled 299 moderate and severe ARDS patients to 20 mg/day dexamethasone for 5 days, which was tapered down to 10 mg/day for another 5 days [19]. Patients receiving dexamethasone had more ventilator free-days on day 28 (6.6 vs 4). However, the 28-day mortality was similar between groups (56.3% vs 61.5%). In the CAPE COVID trial, which enrolled 149 patients, severe ARDS patients received 200 mg/day hydrocortisone [20]. There was no significant difference between groups on day 21 in terms of death or respiratory support (42.1 vs 50.7, $p = 0.29$). All of these studies were included in a prospective meta-analysis. 28-day mortality was lower in those receiving corticosteroids (odds ratio 0.66 [95CI% 0.53-0.82]) [21]. However, questions remain regarding side effects, optimal dosing, administration trigger, or illness severity threshold [22]. Nevertheless, corticosteroids remain the only drug that is shown to be beneficial in severe ARDS patients.

Coinfections and secondary respiratory infections also increase in COVID-19 patients and they are associated with decreased survival. Usually, an elevated procalcitonin (PCT) is found in patients with septic shock. Bacterial infections trigger the synthesis of PCT via interferon- γ . On the other hand, viral infections do not stimulate the same response in the host. Thus, PCT remains mostly normal in the uncomplicated COVID-19 cases and an increased PCT may indicate co-infection in the critically ill patients. A $PCT \geq 0.5$ mg/l indicated a poor outcome in COVID-19 patients with a sensitivity of 88% and specificity of 68% [23].

COVID-19 AND THROMBOSIS

COVID-19 is a hypercoagulable state and it is associated with increased thrombotic events, including pulmonary embolism (PE) [24]. However, the pathophysiology is not fully understood. Very high d-dimer levels may reflect not only systemic inflammation but also thrombosis triggered by the virus [25]. In a retrospective study enrolling 81 COVID-19 pneumonia patients, a D-dimer cut-off value of 1.5 mcg/ml predicted venous thromboembolism (VTE) with 85% sensitivity, 88.5% specificity [26]. In another retrospective study including 127 patients, only D-dimer and CRP levels were found to be associated with VTE. When combined with a D-dimer > 15, a CRP > 280 had a predicted probability of 98% for VTE [27].

The incidence of PE in hospitalized patients is around 1.9%-8.9%. This increases to 26.6% in the critically ill, despite prophylaxis. These numbers are possibly an underestimation of the real incidence as symptoms and findings of PE is nonspecific. For instance, an autopsy of 12 patients revealed deep venous thrombosis (DVT) in 7; none were suspected of having an embolism before death [28]. Nevertheless, routine screening for VTE is currently not recommended [29].

There are several guidelines for laboratory testing in the critically ill with COVID-19. An increase in D-dimer levels (3 to 4-fold (ISTH-IG) or 6-fold (SCC-ISTH) may indicate an embolic event. Regular (not daily) monitoring of platelet count, prothrombin time, and fibrinogen are also recommended [30]. A prophylactic dose of Low Molecular Weight Heparin [LMWH] or subcutaneous unfractionated heparin should be initiated in all suspected or confirmed COVID-19 patients admitted to the hospital [31, 32]. Additionally, mechanical thromboprophylaxis should be considered whenever pharmacological treatment is contraindicated. There is insufficient evidence to suggest mechanical thromboprophylaxis in addition to pharmacological one [30]. Therapeutic anticoagulation should be considered in case of high suspicion of a thromboembolic event. Sudden onset of hypotension or hemodynamic instability should prompt bedside echocardiography. Thrombolytic therapy should be initiated if there is any evidence of right ventricular dilatation or increased pulmonary arterial tension. Other thrombolytic indications include STEMI and acute ischemic stroke [30].

OTHER THERAPIES TO MITIGATE THE EFFECTS OF COVID-19

Although the term “cytokine storm” is broadly defined, it mostly implies an extreme pro-inflammatory response. Manifestations of the cytokine storm include fever, tachycardia, tachypnoea, and vasoplegia leading to hypotension due to endothelial dysfunction and inflammation [33]. Initial reports on observations of severe COVID -19 infection suggested that cytokines, particularly IL-6, played a key role in propagating lung damage and multiorgan failure. A study found that hyperinflammatory type of COVID-19, defined as CRP greater than 150 mg/dl and ferritin greater than 1500 mcg/l, had increased mortality [34]. Subsequently, cytokine removal therapies and monoclonal antibodies targeting interleukins were administered. As of September, there are over 50 interventional studies listed in the clinical trials database for tocilizumab (an anti-IL-6 drug) alone. However, the

presence of a cytokine storm in severe COVID-19 patients is debated. In a healthy volunteer study, plasma IL-6 levels ranged from 1 to 79 pg/ml [35]. On the other hand, patients with ARDS had a median IL-6 concentration of 1618 pg/ml [33], 723 pg/ml [36], 238 pg/ml [37] or 376 pg/ml [38]. Although IL-6 was also increased in patients with COVID-19, the increase is milder compared to ARDS. IL-6 levels of 25, 26 and 64 pg/ml were reported [38]. Furthermore, a single dose of an IL-6 inhibitor can suppress CRP levels and fever for a week and secondary infections can go unnoticed.

Nevertheless, a retrospective observational study in critically ill patients revealed improved mortality among those with baseline CRP levels 15 mg/dl or higher [39]. The authors concluded that tocilizumab may exert its effects in patients progressing to an inflammatory state. It is noteworthy that, tocilizumab was administered on the principal day (a single dose of 400 mg, repeated in case of deterioration) of ICU stay in this study. However, a preprint of the RCT comparing tocilizumab to placebo revealed that tocilizumab failed to improve mortality at day 28. A considerable positive aspect of this study is tocilizumab reduced the duration of ICU stay by 5 days [40].

Extracorporeal cytokine removal therapies have been used for patients with septic shock. The rationale behind the cytokine removal in these patients is to limit the ensuing end-organ damage due to propagated inflammation. Additionally, lung-kidney crosstalk has been proposed recently in ARDS patients [41]. Although the direct mechanism is still not definite, cytokine overproduction and renal medullar hypoxia seem to be relatable [42]. Continuous Renal Replacement Therapy with high and middle cut-off membranes can selectively filter or absorb middleweight molecules, such as IL-6. Subsequently, blood purification therapies were put forward for COVID-19, also. However, only a few case reports reported the benefit of such therapies in this population, and future trials are awaited for definite evidence [43, 44].

Convalescent plasma is collected from the patients who have contracted and recovered from the disease. It has been used for previous pandemics, such as H1N1, SARS, and Ebola, and MERS. Initial case reports showed clinical benefit and reduced mortality in COVID-19 patients, also. Virus load decreased significantly and patients were soon virus negative. A subsequent RCT comparing convalescent plasma to standard treatment showed some clinical improvement in severely ill patients but not in critically ill patients. Likely, pathologic process in those receiving mechanical ventilation and in shock was probably irreversible. Given that the median time between symptom onset and randomization in this study was 30 days, earlier convalescent plasma administration may show better results in the critically ill. Additionally, the study was underpowered to detect significance between the groups. A high-titer antibody may have efficacy against SARS-CoV-2 [45, 46].

CONCLUSION

COVID -19 has caused tremendous constraints on the healthcare system and workers, as well as the patients. The first wave took the clinicians by surprise as many institutions did not have any structured plan to deal with a pandemic; we should not be surprised twice. However, we are now more prepared for patient surges in the intensive care units albeit lacking evidence-based treatment options for the critically ill COVID-19 patients [2].

Chapter 458

ANATOMICAL BASIS OF THE COVID-19

Mehmet Üzel*, MD, PhD and Ö. Alp Taştan, MD

İstanbul University-Cerrahpaşa, Cerrahpaşa Medical Faculty,
Department of Anatomy, İstanbul, Turkey

ABSTRACT

The system most affected by the corona virus disease (COVID-19) is the respiratory system. Typical symptoms of the disease and most of the diagnostic and treatment interventions are related to the respiratory system. In this chapter, we address the basic anatomy of the respiratory system, the anatomical background of some of the respiratory-system-related symptoms of the disease, basic clinical anatomy of some of the diagnostic interventions, and to shed some light on the rationale behind some of the clinical interventions applied during the treatment of the disease. In this chapter, readers will find basic clinical anatomy information about of the nasopharyngeal sampling, tracheostomy, pulmonary volumes and capacities, and effects of the prone position on the prognosis of the patients.

Keywords: anatomy, sampling, prone position

INTRODUCTION

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) affects many systems in the body but most of the typical symptoms of its disease (COVID-19) are related to the respiratory system. The typical symptoms of COVID-19 are fever, dry cough, fatigue, sputum production, and dyspnea [1-3]. When the clinic of the COVID-19 is considered, microbiology, immunology, biochemistry, internal medicine, pharmacology, intensive care, and radiology are some of the medical areas that come into mind firstly; anatomy is not one of them in general. On the other hand, some diagnostic interventions (such as nasopharyngeal and oropharyngeal samplings, bronchoalveolar lavage), some of the clinical interventions

* Corresponding Author's Email: muzel@istanbul.edu.tr.

(such as intubation, tracheostomy, prone positioning) necessitates firm anatomical knowledge to apply them properly or to understand the rationale behind them. This chapter aims to give basic clinical anatomy information about the clinic of the COVID-19.

BASIC ANATOMY OF THE UPPER RESPIRATORY TRACT

Coronavirus transmission occurs via respiratory droplets, and the first entry point is mainly the upper respiratory tract [1, 4]. The upper respiratory tract is the first part of the conducting portion of the respiratory system. Nose, pharynx, and larynx are the main parts of the tract [5, 6].

Nose

The nose is the first part of the airway and can be subdivided into external nose and nasal cavity. Air enters through the external nose, which is the pyramidal-shaped portion that projects from the face, via two elliptical openings called nostrils or nares. These openings are separated by the nasal septum and covered laterally by alae (wings) of the nose. Nostril dimensions vary greatly among individuals. They approximately measure 0,5-1 cm horizontally and 1,5-2 cm anteroposteriorly, with a narrowing in front. The supporting skeleton of the external nose is made up of bone and hyaline cartilage. Bony part is composed of two nasal bones, the frontal process and the anterior nasal spine of maxillae, the nasal part of the frontal bone and, the bony parts of nasal septum. Paired lateral nasal cartilage, which is continuous with septal cartilage, and two alar cartilages form the cartilaginous part [6-8].

Nasal Cavity

The nasal cavity is located between the roof of the oral cavity and the cranial base. It is divided into two halves by the nasal septum, which is formed by the perpendicular plate of ethmoid, vomer, and septal cartilage. The anterior part of the cavity, which is covered by alar cartilage, is called the nasal vestibule. Air enters the cavity via nostrils into the nasal vestibule and travels through the cavity until it reaches the choanae or the posterior nasal aperture, where the nasal cavity opens into the nasopharynx. The adult choanae usually measure 2,5 cm and 1,3 cm in height and width, respectively. Each half of the nasal cavity possesses a roof, a medial and lateral wall, and a floor. The roof can be examined in three parts. The anterior (frontonasal) part is formed by the frontal and nasal bones. This part slopes upwards and backward to form the bridge of the nose. The Central (ethmoidal) part is horizontal and is formed by the cribriform plate of the ethmoid bone which separates the anterior cranial fossa from the nasal cavity. The posterior (sphenoidal) part is a downward-sloping segment that is formed by the anterior part of the sphenoid bone. The floor extends from the anterior to the posterior aperture and has a smooth and concave surface. It slopes up from anterior to posterior. The palatine processes of maxillae and horizontal plates of palatine bones form the floor of the nasal cavity. The medial walls of both halves of the nasal cavity are formed by the nasal septum. The lateral wall is the broadest and the most complicated one among the walls

of the nasal cavity. From anterior to posterior, the maxilla, the labyrinth of the ethmoid, and the perpendicular plate of the palatine bone form the lateral wall. Besides, this wall contains three scroll-like projections of bone called superior, middle, and inferior conchae (turbinates). The superior and middle conchae are medial processes of the ethmoidal labyrinth, whereas the inferior conchae are independent bones. The space underlying each concha is named meatus. Air passes through these meatuses and becomes turbulent. Turbulence keeps air in the cavity for a longer period, so it helps the inhaled air become warmer and humidified. There are several openings which connect the nasal cavity with other structures. The sphenoidal recess, located superoposterior to the superior concha, receives the opening of the sphenoidal sinus, and the superior nasal meatus receives the openings of posterior ethmoidal sinuses. Middle ethmoidal cells form a rounded elevation at the middle nasal meatus called ethmoidal bulla, on which they open. Below the ethmoidal bulla lies a semi-circular groove called semilunar hiatus. The maxillary sinus opens into the nasal cavity via semilunar hiatus. This hiatus curves in front of the ethmoidal bulla and forms a funnel-shaped passage called the ethmoidal infundibulum, which drains the frontal sinus. The inferior nasal meatus is the longest nasal meatus and it receives the opening of the nasolacrimal duct, which drains tears from the lacrimal sac [6-9].

Paranasal Sinuses

Frontal bone, ethmoid bone, sphenoid, and maxilla house air-filled cavities, which are named after the bones they are located in, called paranasal sinuses. These sinuses, lined with respiratory epithelium, help to warm and humidify the inhaled air, add resonance to the voice, and decrease skull bone weight. Only maxillary and ethmoidal sinuses are present at birth. All sinuses enlarge and become fully developed at adolescence [5-8].

Pharynx

Pharynx is a cone-shaped muscular tube which belongs to both alimentary and respiratory systems. It lies between the cranial base and C6 vertebra, posterior to nasal cavities, oral cavity, and larynx. Pharynx has three parts; nasopharynx, oropharynx, and laryngopharynx. Choanae connects the nasal cavities to the nasopharynx, isthmus of fauces (oropharyngeal isthmus) connects the oral cavity to the oropharynx, and the laryngeal inlet connects the laryngeal cavity to laryngopharynx. The nasopharynx is found above the soft palate behind nasal cavities. Mucosa covering the inferior part of the body of the sphenoid and the basilar part of the occipital bone form the roof and the superior portion of the posterior wall of the nasopharynx. In the middle part of the junction of the roof and the posterior wall, a lymphoid tissue called the pharyngeal tonsil (adenoid) is found. The pharyngeal opening of the pharyngotympanic (Eustachian) tube occupies the lateral wall of the nasopharynx on both sides. The opening is located approximately 1 cm posterior and just below the posterior end of the inferior nasal concha. The superoposterior part of the opening has an elevation called torus tubarius. Under the mucosa covering the torus tubarius, a mass of lymphoid tissue, called tubal tonsils (Gerlach's tonsil), can be found. The salpingopharyngeal fold, which

covers the salpingopharyngeal muscle, descends posterior to the torus tubarius. A small depression, called pharyngeal recess (fossa of Rosenmüller), which extends posteriorly and laterally, is also located posterior to the torus tubarius. The oropharynx is the middle part of the pharynx and is located posterior to the oral cavity, between the soft palate and the superior border of the epiglottis. It has both digestive and respiratory functions. The anterior part of its lateral wall is bordered by two arches; palatoglossal arch and palatopharyngeal arch. Palatine tonsil is located between these two arches. The inferior part of the anterior wall of the oropharynx is made by the root of the tongue. There is a collection of lymphoid tissue under the mucosa covering the root of the tongue, called lingual tonsil. Single pharyngeal tonsil, bilateral tubal tonsils, bilateral palatine tonsils, and single lingual tonsil form a lymphoid ring at the pharynx. This ring is called the pharyngeal lymphoid ring or Waldeyer's ring. It acts as the first line of defense for infections. Laryngopharynx is the inferior part of the pharynx. It is located between hyoid bone (the level of C3 vertebra) or the upper margin of the epiglottis and the inferior border of the cricoid cartilage (the level of C6 vertebra) or the superior border of the oesophagus. Laryngeal inlet is located on the anterior wall, and has two depressions on each side, called piriform fossa (recess) [5-9].

Larynx

Larynx is a specialized organ that functions as a sphincter for air passage and responsible for voice production. It is located at the anterior part of the neck, between laryngopharynx and trachea. The supporting skeleton of the larynx is composed of hyaline cartilages, which are connected by membranes and ligaments, and moved by muscles. There are nine cartilages that forms the framework; thyroid cartilage (1), cricoid cartilage (1), epiglottis (1), arytenoid cartilage (2), corniculate cartilage (2), and cuneiform cartilage (2). Thyrohyoid membrane is a broad structure that connects the hyoid bone to the superior border of thyroid cartilage. Internal branch of the superior laryngeal nerve and the superior laryngeal vessels pass through this membrane. Cricotracheal ligament attaches the cricoid cartilage to the first ring of the trachea. Quadrangular membrane is stretched between the lateral border of the epiglottis and anterolateral face of the arytenoid cartilage on the same side. The free inferior border of this membrane thickens to form the vestibular ligament which then constitutes the vestibular fold when covered with mucosa. Cricothyroid membrane extends between thyroid cartilage and cricoid cartilage. In cases of emergency (laryngeal obstruction), it is recommended to perform a laryngotomy at the site of this membrane. Conus elasticus (cricovocal membrane) also attaches to the superior border of cricoid cartilage inferiorly but it has a free superior border which forms the vocal ligaments on each side. Vocal ligaments then form the vocal folds when covered by mucosa. The gap between the vocal folds is called rima glottidis. The muscles of larynx can be categorized as extrinsic and intrinsic muscles. Extrinsic muscles (digastric, stylohyoid, mylohyoid, geniohyoid, stylopharyngeus, salpingopharyngeus, palatopharyngeus, sternothyroid, sternohyoid, omohyoid muscles) are mainly responsible for elevation and depression of the larynx whereas the intrinsic muscles (oblique arytenoid, transverse arytenoid, thyroepiglottic, cricothyroid, thyroarytenoid (vocalis), lateral cricoarytenoid, posterior cricoarytenoid muscles) are responsible for phonation and sphincter function of the larynx [5-9].

ANATOMY OF OLFACTORY DYSFUNCTION

The lining of the nasal cavities consists mainly of respiratory epithelium, except for the nasal vestibule and the olfactory cleft where the olfactory epithelium is present [6]. The olfactory epithelium (mucosa) contains olfactory receptor nerve cells, which enter through the cribriform plate of the ethmoid bone [8]. Olfactory mucosa lines approximately 5-9 cm² of the total 150 cm² mucosal area covering the nasal cavities, including structures that are superoposteriorly located in the nasal cavity [6, 10]. The spike of SARS-CoV-2 uses the host receptor Angiotensin-Converting Enzyme 2 (ACE2), which is found abundantly in the respiratory epithelium, to enter the cells [1, 3]. The olfactory epithelium and respiratory epithelium are closely related, so it is only natural for COVID-19 to cause olfactory dysfunction due to the neurotropic properties of the virus [10, 11].

ANATOMY OF OCULAR TRANSMISSION

Lacrimal gland, which is located in the superolateral portion of the orbit, constantly produces tears [6, 7]. Some tears are absorbed by cornea and conjunctiva or evaporate [6, 12]. Remaining tears are drained by lacrimal canaliculi into the lacrimal sac. Then tears pass through a 12 mm long nasolacrimal duct to reach the upper respiratory tract via an opening located at the inferior nasal meatus [6, 12]. This transport allows pathogens like SARS-CoV-2 from conjunctival or corneal epithelium, which expresses ACE2, to be transferred to the respiratory epithelium [10, 12].

ANATOMY FOR UPPER RESPIRATORY TRACT SAMPLING

For diagnostic testing for SARS-CoV-2 in patients who meet the diagnostic criteria, that are put forward by World Health Organization (WHO), Central for Disease Control and Prevention (CDC) recommends collecting upper respiratory system specimens [1, 13]. These samples include nasopharyngeal swaps, oropharyngeal swaps, mid-turbine swap, nasal swab, and nasopharyngeal wash/aspirate or nasal wash/aspirate [1, 13, 14]. Anatomy knowledge of the respiratory system is required to collect these specimens safely and correctly [4, 15]. Nasopharyngeal and oropharyngeal swaps are frequently used [4], therefore anatomic considerations for both will be discussed below.

Nasopharyngeal Swab

Nasopharyngeal swap is recommended by WHO as a reference diagnostic method in COVID-19 [16]. Specimen is collected by inserting a flexible swab stick through the nostril [13]. Tilting the patient's head slightly posterior is recommended to make the nasal passages more accessible [4, 17]. The swap is inserted parallel to the palate along the floor of the nasal cavity until encountering a resistance that indicates contact with the nasopharynx or reaching

the estimated distance [4, 13]. The distance between nostrils to the nasopharynx is approximately 9,4 cm in females and 10 cm in males [18]. The required distance can also be estimated by measuring the distance between nostrils (or the philtrum) and tragus, which is roughly 5 cm longer than the distance between nostrils and the nasopharynx in both genders [4, 13, 18]. The swap should not be directed medially, because the nasal septum contains anastomosis of arterioles and veins that are prone to bleeding [4, 6]. The most notable one is the Kiesselbach's plexus (Little's area) which is formed at the anterior part of the nasal septum by the anterior ethmoidal artery (from the ophthalmic artery), the posterior ethmoidal artery (from the ophthalmic artery), the sphenopalatine artery (from the maxillary artery), the greater palatine artery (from the maxillary artery), and the septal branch of the superior labial artery [4, 6, 7].

Oropharyngeal Swab

Oropharyngeal swab shows a lower positive rate than nasopharyngeal swab but has a lower risk of bleeding compared to nasopharyngeal swab [2, 4]. The swab is inserted through the mouth and the specimen is collected from the posterior wall of the oropharynx and over the palatine tonsils.

BASIC ANATOMY OF THE LOWER RESPIRATORY TRACT

The airways below the larynx are collectively called tracheobronchial tree. The tracheobronchial tree is morphologically divided into trachea, bronchi, bronchioli, and alveoli.

Trachea is the first and most superior part of the tracheobronchial tree. The trachea is mobile and has a tubular form. It starts from the lower border of the cricoid cartilage of the larynx at the C6 vertebra level and ends at the tracheal bifurcation at the level of the intervertebral disc between T4 and T5 vertebrae. The tracheal bifurcation may rise about one vertebral level during expiration, and lower to T6 vertebral (or manubriosternal junction, i.e., angle of Louis) level during deep inspiration. The length of the trachea is between 10 and 15 cm [6, 9], and its cross-sectional area is about 3 cm² in adults [19]. The size of the trachea is correlated with the size of the person. The general rule is that the width of the trachea is the same as the diameter of the index finger of the same person. The external transverse diameter of the trachea is approximately 2-2,5 cm in adult males, approximately 1,5 cm in adult females, and approximately 0,5 cm in infants [6, 7, 20]. It consists of 16-20 C-shaped hyaline cartilages. These cartilages are oriented horizontally, and their convex surfaces are directed anteriorly. A fibroelastic tissue connects tracheal cartilages. Because the tracheal cartilages are C-shaped and the posterior wall, which is composed of smooth muscle (i.e., tracheal muscle), is flattened, the cross-section of the trachea is D shaped.

The cervical part of the trachea is between the lower border of the cricoid cartilage and the thoracic inlet. This part of the trachea has important relations regarding the tracheostomy. The jugular arch, sternohyoid and sternothyroid muscles, isthmus of the thyroid gland (in front of the 2.-4. tracheal cartilages), an anastomotic branch of the superior thyroid arteries,

inferior thyroid veins, thyroid ima artery (variation) are located anteriorly; in children, the brachiocephalic trunk crosses in front of the trachea at or a little above the upper border of the manubrium of the sternum. The oesophagus is posterior to the trachea. The common carotid arteries, inferior thyroid arteries, lobes of the thyroid glands are located lateral to the trachea. The recurrent laryngeal nerves ascend in the tracheoesophageal groove. The cervical part is supplied by inferior thyroid artery, and innervated by the vagal branches and sympathetic trunk [6].

The thoracic part of the trachea is located within the superior mediastinum. It bifurcates at the level of the sternal angle (manubriosternal junction, angle of Louis) into two main bronchi for each lung, passing inferolateral to enter the lungs at their hila. The right main bronchus is wider, shorter, and runs more vertically than the left one as it passes directly to the hilum of the lung. The left main bronchus passes inferolateral, inferior to the arch of the aorta and anterior to the esophagus and thoracic aorta, to reach the hilum of the lung. Because of differences in sizes and directions of the two main bronchi, inhaled foreign bodies tend to enter the right bronchus [6, 7, 20]. The cartilage at the tracheal bifurcation is the carina. If the sharp edge of the carina becomes flattened, this usually indicates enlargement of the hilar lymph nodes or gross distortion of the pulmonary anatomy by fibrosis, tumor, or other pathology [9].

Within the lungs, the bronchi branch to form the rest of the branches of the tracheobronchial tree. Each primary (main) bronchus divides into secondary (lobar) bronchi, each of which supplies a lobe of the lung. Each secondary bronchus divides into tertiary (segmental) bronchi that supply the bronchopulmonary segments. The bronchopulmonary segments are the largest subdivisions of a lobe. They have a pyramidal shape, and their apices are directed towards the root of the lung. They are supplied independently by a segmental bronchus and a tertiary branch of the pulmonary artery. There are usually 10 segments in each lung, but this number is subject to variation. Because each segment has separate bronchial, vascular, lymphatic, and nervous supply, they are surgically resectable [6, 7, 20]. After the tertiary segmental bronchi, bronchioles start. There are 20-25 generations of bronchioles that end as terminal bronchioles. Bronchioles lack cartilage in their walls. Each terminal bronchiole gives rise to several respiratory bronchioles, which have alveoli extending from their lumens. The pulmonary alveolus is the basic structural unit of gas exchange in the lung. Each respiratory bronchiole gives rise to 2-11 alveolar ducts, each of which gives rise to 5-6 alveolar sacs. Alveolar ducts are elongated airways densely lined with alveoli, leading to the alveolar sacs, into which alveoli open. The total number of the alveoli in the adult is between 300-400 million [6, 7, 20, 21], and the total surface area is approximately 140 m² [19].

ANATOMY OF THE TRACHEOSTOMY

Tracheostomy is the creation of a hole in the anterior aspect of the trachea. This intervention is applied during clinical situations such as upper airways obstructions, laryngeal and craniofacial traumas, laryngeal edema, and laryngeal cancers. The hole can serve independently, or a tube can be inserted through it. After identifying the thyroid and cricoid cartilages, the neck is extended, and a vertical incision is made from the cricothyroid membrane to the suprasternal notch. Superficial fascia and the fibers of the platysma are

dissected (anterior jugular veins should be avoided), investing fascia is incised, the pretracheal muscles are split. Depending on the decision of the physician, the second tracheal ring (which is superior to the isthmus of the thyroid gland), third to fifth tracheal rings (after dissecting the isthmus of the thyroid gland), or tracheal rings below the isthmus can be cut. The major structures around the trachea should be avoided during the procedure [6, 20].

BASIC ANATOMY OF THE LUNGS

Lungs are soft and spongy organs, which are essential for respiration. Each lung consists of lobes, which are two on the left and three on the right side. Each lung is situated in the thoracic cavity on both sides of the mediastinum in their pleural cavities. In adults, right lung weighs approximately 620-625 g, and the left 565-570 g [6, 8, 9].

Each lung has a cone shape and has apex, base, three borders, and two surfaces. The apex of the lung is the part that extends superiorly through the thoracic inlet. It rises 3-4 cm above the first costal cartilage and is in contact with the cervical pleura, which is covered by suprapleural membrane (Sibson's fascia). The tip of the apex is 2,5-4 cm above medial third of the clavicle [6, 8, 9]. Base of the lung is deeply concave and sits on the diaphragm. Because the right half of the diaphragm is higher, the base of the right lung is deeper [6]. The costal surface is smooth and relates to the thoracic wall. The posterior costal surface is vertically longer than the anterior surface [6, 9]. The mediastinal surfaces of the lungs constitute the lateral walls of the mediastinum. The left mediastinal surface is closely related to the left ventricle and auricle, the arch of aorta, the left subclavian and common carotid arteries, left brachiocephalic vein, trachea, oesophagus, the left vagus, and the thoracic duct. The right mediastinal surface is closely related to the right atrium and right ventricle, superior and inferior vena cava, the azygos vein, the trachea, the right vagus, and phrenic nerves [6, 9]. The most peculiar feature of the mediastinal surface is the hilum, which is the site of entry and exit for the principal bronchus, pulmonary artery, pulmonary veins, bronchial vessels, pulmonary autonomic plexus, and lymphatic vessels. All these structures are enveloped by a pleural sleeve and are collectively called pulmonary root.

COUGH REFLEX

Cough is one of the most important defensive mechanisms of the respiratory system, and one of the most common symptoms of COVID-19 infection [1]. It clears the secretions and particles from the airways and serves protection against foreign material (including inflammation and mediators associated with inflammation) aspiration. The trachea (especially carina) and bronchi are very sensitive to light touch, and the terminal bronchioles and the alveoli are sensitive to corrosive chemical stimuli. Afferent nerve impulses from the airways pass mainly through the vagus nerves (CN X) to the medulla of the brain. There, an automatic sequence of events causes some sequential events: 2,5 L of air is inspired rapidly, the epiglottis and glottis close, abdominal and internal intercostal muscles contract forcefully, the pressure inside the lungs rises to 100 mmHg, the epiglottis and glottis open, air inside the lungs expelled with a very high velocity (75-100 miles/hour) [6, 22].

PLEURA

Pleura is the serous membrane covering all the surfaces (except the hilum) of the lung, internal surface of the thoracic wall, and most of the superior surface of the diaphragm. Each lung has its own pleura. The pleura has two layers which are named according to their site of attachment: parietal pleura is attached to the thoracic wall and diaphragm, and the visceral pleura to the lung parenchyma [6, 9].

MUSCLES OF RESPIRATION

Respiration has two phases: inspiration and expiration. While the quiet and forced inspirations are active (accomplished by muscular activity), the expiration is passive (accomplished by elastic recoil of the tissues) in quiet respiration but active in forced expiration. The muscles of respiration can be divided into two groups: inspiratory muscles and expiratory muscles. The primary inspiratory muscles are the diaphragm and the external intercostal muscles; secondary inspiratory muscles are sternocleidomastoid, scalene (anterior, middle, and posterior) muscles, and pectoralis major and minor. Primary expiratory muscles are the internal and innermost intercostal muscles; secondary expiratory muscles are transversus thoracis, subcostals, serratus posterior inferior, rectus abdominis, external and internal obliques, transversus abdominis, latissimus dorsi, and quadratus lumborum [6, 23]. Depending on the muscles used during inspiration, breathing can be grouped in two types: abdominal (diaphragmatic) breathing uses the diaphragm as the power generator, while the thoracic breathing uses external intercostal muscles as the power generator. Infants and small babies have ribs lying horizontally and weak intercostal muscles, so the diaphragm and abdomen are the primary means of ventilation [21].

PULMONARY VOLUMES AND CAPACITIES

Pulmonary volume (also known as lung volume or respiratory volume) refers to the volume of air in the lungs at a given phase of the respiratory cycle. A combination of the pulmonary volumes is called pulmonary capacity. There are four pulmonary volumes and four pulmonary capacities. The tidal volume is the volume of air inspired or expired with quiet respiration (~0,5L). The inspiratory reserve volume is the extra volume of air that can be inspired when the person inspires with full force (~3L). The expiratory reserve volume is the maximum extra volume of air that can be expired after the end of the tidal expiration (~1,1L). The residual volume is the volume of air remaining in the lungs after the most forceful expiration (~1,2L) [22]. The inspiratory capacity is the sum of the tidal volume and the inspiratory reserve volume (~3,5L). The functional residual capacity is the sum of the expiratory reserve volume and the residual volume (~2,3L). The vital capacity is the sum of the inspiratory reserve volume, the tidal volume, and the expiratory reserve volume (~4,6L). The total lung capacity is the maximum volume to which the lungs can be expanded with the maximum effort and is the sum of the vital capacity and the residual volume (~5,8L) [22].

EFFECT OF THE PRONE POSITION ON THE VOLUMES, PERFUSION, AND VENTILATION OF THE LUNGS

During the COVID-19 pandemic, the media shared different images of hospitalized patients lying in prone position (PP) in intensive care units. PP is being used since 1970s to treat hypoxemia in patients who have acute respiratory distress syndrome (ARDS) [19, 24]. Treatment of the ARDS requires tracheal intubation and mechanical ventilation. PP was shown to be beneficial in ARDS patients; it may even postpone or avoid tracheal intubation [25]. PP improves gas exchange [19, 24, 25], provides more even tidal volume distribution in the lungs [24], improves resting lung volume in the dorsocaudal regions of the lungs [24], improves ventilation-perfusion relationship [19, 24, 25], improves peripheral oxygen saturation [25], ameliorates the severity or development of ventilator-induced lung injury [25], improves clearance of lung secretions [26], reduces neutrophil and pro-inflammatory mediator levels (IL-1 β , IL-6, and 1 IL-8) in bronchoalveolar lavage fluid [24] and improves mortality in ARDS patients [19, 24, 25]. PP is most effective in improving oxygenation when initiated during the exudative phase of the ARDS [24]. PP improves lung mechanics, which occurs via changes in anatomical relationships.

PP has effects on the transpulmonary pressure (Ptp), and ventrodorsal transpulmonary pressure difference. The Ptp is defined as the difference between the alveolar pressure (Pal) and pleural pressure (Ppl). In supine position (SP), the dorsal Ppl raises (because of the compressive effect of the lung weight on the dorsal parts of the lung) and Ptp diminishes; ventral Ppl diminishes and Ptp increases. The net result is ventral alveoli are overinflated and the dorsal alveoli are underinflated (atelectasis) [19, 25, 27, 28]. PP diminishes the difference between ventral and dorsal Ptp; when the patient is in PP, larger mass of lungs is suspended from a wider posterior chest area and Ppl diminishes at the dorsal parts of the lungs. Because of this, dorsal Ptp increases, dorsal alveoli open, ventilation in the dorsal parts of the lungs improves, difference between ventral and dorsal Ptp decreases, and more uniform ventilation is achieved [19, 24, 27, 29].

The effect of the PP on the perfusion of the lungs is slight [27] and pulmonary perfusion is preferentially distributed to the dorsal lung regions in both SP and PP [24]. Because perfusion is unaffected and ventilation is diminished in the dorsal part of the lungs, V/Q ratio diminishes (V/Q mismatch). This mismatch creates a physiological shunt in the dorsal part of the lungs [29]. In PP, dorsal alveoli are inflated, ventilation is improved, V/Q mismatch improves, intrapulmonary shunt decreases (~50%) and oxygenation improves [24, 29].

When an ARDS patient lies in SP, the heart and diaphragm compress the dorsal lung parenchyma. Because of the compression of the lungs by either structure, hypoxemia increases, and ventilator-associated lung injury worsens [19, 24, 27, 29] and this effect is exacerbated by obesity [19]. In PP, heart lies on the sternum, compression of the heart on the dorsal lung parenchyma decreases, ventilation and oxygenation improves.

PP reduces neutrophil and pro-inflammatory mediators (IL-1 β , IL-6, and IL-8) levels in bronchoalveolar lavage fluid. Of particular interest is IL-8, which is a chemo-attractant cytokine for neutrophils and secreted by the alveolar epithelium and macrophages in response to excessive stretch. The result of the neutrophil infiltration is proteolytic enzyme release that causes lung injury. PP creates more homogeneous pleural pressure gradients and more

uniform strain-stress relationships throughout the lungs, so the stretch is released, IL-8 is secreted less, neutrophil attraction and lung injury diminishes [24].

In SP, ventral parts of the lungs are overinflated and overdistended, and dorsal parts open and collapse cyclically during mechanical ventilation. These changes cause ventilatory-induced lung injury that increases IL-6 expression. Another cause for increased levels of IL-6 is hyperoxemia during mechanical ventilation. In PP, ventilation becomes uniform in the lungs, need for mechanical ventilation diminishes, and FiO₂ lowers rapidly. As a result, IL-6 levels decrease [30].

CONCLUSION

For a proper and effective treatment of a disease, firm knowledge of pathology and pathophysiology of that disease is necessary. In COVID-19, the anatomy does not seem to be related to the clinic of the disease. However, basic clinical anatomy knowledge is necessary during some diagnostic (nasopharyngeal sampling, oropharyngeal sampling) and therapeutic (tracheostomy, prone positioning) treatments. Physicians applying those treatments should be aware of the potential risks, their prevention, and treatment, as well.

Chapter 459

GENETIC BACKGROUND OF DIFFERENCES IN THE INCIDENCE OF CORONA VIRUS INFECTION

R. Dilhan Kuru*, PhD and İlhan Onaran, PhD

Istanbul University- Cerrahpasa, Cerrahpasa Medical Faculty,
Department of Medical Biology, Istanbul, Turkey

ABSTRACT

Variability in susceptibility and disease severity in response to viral exposure is a distinctive feature of infectious diseases. It has also been noted a wide range of inter-individual variations in the infectivity, disease severity, and progression of COVID-19. Furthermore, it has been observed that susceptibility to COVID-19 shows geographical variation. Increasing evidence suggests a major role for host genes that affect viral infectivity and pathogenicity in explaining inter-individual and ethnic differences in susceptibility to coronavirus infections. Comparison of more than half a million genetic variants in individuals with the disease and population controls shows that many genes might be involved in susceptibility to COVID-19 infection. Some hypotheses have been proposed to explain how genes play a role in determining or influencing the efficacy of infection, the immune response to infection, or the severity of COVID-19 symptoms. These hypotheses include several genomic variants in the Angiotensin-Converting Enzyme, TMPRSS2, histocompatibility complex class I, and other few genes, the ABO blood group polymorphism, epigenetic alterations regulating host response, and telomere shortening. Throughout the recently published literature, we will discuss the recently published literature on host genetic factors related to coronaviruses, focusing on human studies in the context of COVID-19 susceptibility, severity, and progression as well as in geographical variation.

INTRODUCTION

One of the most important research questions on the ongoing severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) pandemic is why some people are more susceptible than others to SARS-CoV-2? Additionally, it is now evident that susceptibility to COVID-19 shows geographical variation. There are enormous clinical variabilities between individuals infected with SARS-CoV-2. This condition is ranged from silent to fatal infections [1]; the reason for this is currently not clear. Hypotheses suggested explaining observed differences include age, biological sex, other prior existing health conditions, and genetic factors. A twin study reported that 50% of the variance of the ‘predicted covid-19’ phenotype is due to genetic factors [2]. As with many complex diseases, the reality for most individuals most likely involves a complex interaction of genetic (viral and host genetics) and non-genetic variables. As related to hosting genetic factors, multiple *in silico* and molecular prediction studies show that multiple genes can be crucially involved in infection and progression of COVID-19. The scientific community suggests that single nucleotide polymorphisms (SNPs), or commonly known gene polymorphisms in the angiotensin-converting enzyme (ACE2), the transmembrane serine protease 2 (TMPRSS2), and other few genes reported, genetic variability in major histocompatibility complex (MHC) class I genes (human leukocyte antigen [HLA] A, B, and C), the ABO blood group polymorphism, epigenetic changes that might affect viral entry and replication, and excessive immune response to the virus, and telomere shortening may influence susceptibility to SARS-CoV-2 infection and the outcome of the COVID-19 disease. The preliminary results from the COVID-19 host genetics consortium which was established to discover and study the human genetic variants that modulate the susceptibility of developing COVID-19 symptoms and severity show several suggestively associated loci. However, very little is understood about the role of gene networks in determining or influencing the efficiency of infection and progression of COVID-19. Understanding these gene networks can situate susceptible individuals/populations, inform personalized treatment, and help vaccine development.

Throughout the recently published literature, we will focus on the most studied genetic variations which play a pivotal role in determining or influencing the efficacy of infection, the immune response to infection, or the severity of COVID-19 in the context of human studies.

ASSOCIATION OF SEX CHROMOSOMES WITH COVID-19

Gender difference has always been interesting in infectious disease research according to the World Health Organization (WHO) (as of April 18th, 2020). The male to female ratio among confirmed cases is 1.03:1 with a median age of 51 (interquartile range, IQR: 36–65) years [<https://www.who.int/emergencies/diseases/novelcoronavirus2019/situation-reports>. Accessed 25 Apr 2020]. Interestingly, the International Organization for gender equality and health equity Global Health reports sex-disaggregated data as 50/50. The gender difference in response to COVID-19 infection may play a larger role in the clinical disparity. Often reported, men are more susceptible to coronavirus infection and severe prognosis of the disease. On the other hand, studies shown that Sry expression on the Y chromosome is related to the reduction of the immune response. As known, the X chromosome has about 3000

different genes and encoding for more than 800 miRNAs. Genes of importance for immune response are encoded on the X chromosome. X chromosome inactivation (XCI) provides an equivalent gene dosage for both sexes [4].

X Linked Genes and X Inactivation

During early female embryogenesis, one of the X chromosomes is inactivated to have an equal dosage in the products of X-linked genes in males and females [5, 6]. The XCI process is formed by a multistep epigenetic mechanism. However, inactivation is not uniform and one-third of X-chromosomal genes escape from inactivation. XCI is incomplete in humans with one-third of X-chromosomal genes been expressed from both active (Xa) and inactive (Xi) X chromosomes in human female cells. These genes that escape X inactivation have been called ‘escapers’. Many of these genes are located at the ends of each arm of the X chromosome in areas known as pseudoautosomal regions (PAR1 and PAR2). These regions are present on both sex chromosomes. The genes that escape from X-chromosome inactivation may transcribe as two working copies [7]. There are other genes escaping from XCI, besides the genes in the PAR regions. These genes are defined as showing >10% expression from the inactive X allele compared to the active X allele [8]. In addition, the evidence was reported that at least 23% of X-linked genes continue to be expressed by the inactive X chromosome, and this condition is leading to a female bias less than two folds in the expression levels [9]. These regions escaping from XCI are including immune-related factors. For example, toll-like receptors (TLRs) [4], and *ACE2* gene are biallelically expressed in females in keeping with their location to Xp22 within a chromosome region prone to escape XCI. The *TIMP1* (tissue inhibitor of metalloproteinase 1) gene encoding proteins involved in response to infections and septic shock, maps to Xp11, within a region enriched in dosage-sensitive genes with a low chance of escaping XCI and is characterized by a variable expression from the inactive X chromosome. However, there are regions with immune-related genes escaping silencing in female lymphocytes, such as *CXCR3* at Xq13, encoding a chemokine receptor and *CD40L* at Xq16 encoding CD40 ligand, a B cell costimulatory molecule member of the tumor necrosis factor (TNF) family, for which biallelic expression is restricted to some mature B and T cells. Because of a functional advantage, these cells become overexpressed in tissues involved in the immune response. In addition, it has been suggested that there are miRNA-223 at Xq12, a fine tuner of granulocyte production and the inflammatory response, and miRNA-424 at Xq26, regulating monocyte/macrophage differentiation [10]. Different females may have different levels of mosaicism according to the percentage of the cell population with the parental X chromosome preferentially inactivated. This process may occur randomly or by selection against the cell population with a pathogenic variant on the active X. But 10% of healthy females over 50 years have haploinsufficiency for X-linked genes in immune-related cells with reduction of variation in their expression, losing their advantage compared to males. It has been shown that females have the capability to stronger and adaptive immune response than males. Likewise, Larissa said that X-linked genes may have a role in the emergence and maintenance of different immune reactions against COVID-19 in women and men, but there is no study on this issue yet [11].

Toll-Like Receptor 7 (TLR7)

Anti-viral immunity includes both innate immune and adaptive immune responses. Innate immune receptors have two main varieties as transmembrane and cytosolic. This situation is important for innate immunity, and thus adaptive for immune responses. Toll-like receptors (TLRs) are a family of sensor proteins that help the immune system to differentiate between “self” and “non-self.” TLR 3, 7, 8, and 9 are immune receptor which play role in host survival to viral infection [12]. They can detect the complete viral particles, including viral nucleic acid and viral envelope proteins, and defective viral particles [13]. Upon recognition of a virus, TLR signaling upregulates the expression of pro-inflammatory cytokines and costimulatory molecules, by the accumulation of type I interferons (IFNs) and IFN-stimulated genes (ISGs) [14, 15].

TLR7 activating by synthetic ligands such as imidazoquinolines is an endosomally located sensor. It is also a key component of antibody-mediated immunosuppression against the reactivation of endogenous retroviruses [12]. TLR7 detect single-stranded RNA viruses. It is expressed on variable immune cells such as plasmacytoid dendritic cells, B lymphocytes and myeloid cells, and non-immune cells including hepatocytes, epithelial cells, and keratinocytes [4]. After ligand binding, TLR7 dimerizes and activates signaling pathway involving myeloid differentiation primary response gene 88 (MyD88), mitogen-activated protein kinase (MAPK) cascades, NF- κ B activation, as well as IFN regulatory factor (IRF)-7 and IRF-5 activation via IL-1 receptor-associated kinases (IRAK)-1/2/4 and TNF receptor-associated factor-3/6. As a result, pro-inflammatory cytokines (TNF- α , IL-6, IL-1 β , IL-12) and IFN- α are produced, and TLR7 may stimulate B cells to enhance antibody production [12]. It is reported that IL-6 is very important in the dysregulated host immune response of poor prognosis COVID-19 patients [16]. The lower susceptibility to viral infections in females is observed from birth to adulthood. It is accepted that females develop stronger innate and adaptive immune responses than males. The activity of the innate immune response was reported to vary between males and females. Firstly, the TLR7 expression level is increased in women. Biallelic expression of TLR7 has been found in immune cells of women (and Klinefelter syndrome males) and this results in higher TLR7 protein expression in leukocyte populations of females [12]. Secondly, higher IFN- α production in females was demonstrated by several *in vitro* studies using stimulation with synthetic TLR7 ligands. Berghöfer et al. suggested that female peripheral blood lymphocytes produced much higher IFN- α levels than males after TLR7 stimulation by a large cohort study of healthy individuals [16]. TLR7 expression is higher on the immune cells of females after puberty. Also, in XX females IFN- α production was always above than monosomy X (Turner’s syndrome) females and XY males [4]. So, males have a relatively reduced antiviral immunity, since they produce a lesser amount of IFNs and inflammatory cytokines and possess a lower number of circulating T cells [11, 13]. Although females have stronger immunity, they also develop more autoimmune diseases than males [4].

HOST GENETIC FACTORS RELATED TO SARS-CoV-2 ENTRY INTO HOST CELLS

Host genetic studies using both candidate-gene and genome-wide strategies approaches identified significant associations between SARS-CoV-1 susceptibility or outcome and genetic variations such as single nucleotide polymorphisms in the human genome. Some of these genetic variations are associated with the human genes required for SARS-CoV/CoV-2 entry. The endosomal cysteine protease cathepsin B and L, TMPRSS2, glucose-regulated protein 78 kDa (GRP78), and ACE2 are commonly exploited by SARS-CoV/CoV-2 for cellular entry. Single nucleotide polymorphism variants in the genes for these proteins have significant differences in frequencies among the population groups. Also, several polymorphisms of genes required for SARS-CoV/CoV-2 entry has linkages with diabetes, cardiovascular disease, and hypertension, which, as comorbidities, significantly increase the severity of virus infection.

ACE2 and TMPRSS2

When coronaviruses, as well as influenza viruses, invade the target cells, usually the lungs, they need two proteins in the cell membrane, ACE2 receptor, and TMPRSS2. Following the surface spike proteins on the viral capsid attach to the ACE2 receptor, the virus initiates non-endosome entry of its genome across the cell membrane with the assistance of TMPRSS2, which catalyzes the cleavage of the bound spike protein. Thus, it causes a conformational change that promotes the fusion of viral and cellular membranes and thereby allows the release of the virus into the cell.

As regards the role of host genetic factors in coronavirus susceptibility or outcome, the human ACE2 has a rich pool of rare variants and is one of the most studied genes. The SARS-CoV-1 and COV-2 genomes shared around 80% of homology and used the same ACE2 to enter the cell [17]. Comparative genetic analyses of data from different databases indicate that several ACE2 variants could reduce the association between ACE2 and S-protein in SARS-CoV [18]. Several studies also suggest that the expression level and expression pattern of human ACE2 in different tissues might be critical for the susceptibility and progression of 2019-nCoV/SARS-CoV-2. Although a study group did not identify genetically supporting the existence of coronavirus S-protein binding-resistant ACE2 mutants in different populations by using the GTEx database [19], another group demonstrated that certain variants in the gene (rs73635825 and rs143936283) result in different intermolecular interactions with SARS-CoV-2 spike protein [20]. Hussain et al. [20] by a comparative modeling and molecular super-imposition study revealed that ACE2 alleles, rs73635825, and rs143936283 have a low binding affinity for SARS-CoV-2 spike protein. Therefore, these alleles may lead to resistance against COVID-19. It has been generally accepted that the ACE2 genetic variants may influence the protein's binding to the virus and its subsequent invasion of the cell. Although the frequencies of allelic variants of the ACE2 varies from one country to another [21], the genetic basis of ACE2 expression and function in different populations is still largely unknown.

Although it has been known that increased TMPRSS2 expression is related to two SNPs (rs2070788 and rs383510) and the susceptibility to H7N9 influenza [22], it has received less attention in genetic association studies to date. An in vitro study showed that a cell line expressing TMPRSS2 is highly susceptible to SARS-CoV-2 infection [23]. Recently, it has been recognized that SARS-CoV-2 uses the cellular protease TMPRSS2 for S protein priming. Russo et al. [24] published that the lung-specific expression quantitative trait loci (eQTL) variants for TMPRSS were associated with increased expression of TMPRSS2. They suggested that the eQTL variants may confer different susceptibility or response to SARS-CoV-2 infection. However, further research is needed to determine if these genetic variants in COVID-19 susceptibility, incidence, and progression.

Interferon (IFN)-Induced Transmembrane (IFITM)

It is generally postulated that RNA virus entry into cells by endocytosis is regulated with interferon (IFN)-induced transmembrane (IFITM) proteins, which confer cellular resistance to many pathogenic viruses by preventing viral fusion with cholesterol depleted. IFITM3, the most potent antiviral IFITM, inhibits an early event after endocytosis of virion particles. Sequence variants of the IFITM3 gene exhibit ethnic differences [25]. Among these variants, the polymorphism rs12252 C allele is considered to produce an alternate spliced transcript that encodes an aberrant truncated protein of IFITM3. Zhang et al. (2013) found a significant association between the IFITM3-rs12252CC genotype and influenza severity and hypothesized that the high frequency of the C allele in Asian populations may influence the epidemiology of influenza since this genotype was the much higher in the Han Chinese population compared with Caucasians [25]. A recent Indian study by a clinical exome data of 103 individuals also identified this genotype as risk inducing for SARSCoV-2 infection [26]. In the same study, one IFITM3 polymorphism, rs34481144 is also proposed as a protective variant for COVID-19 by increased memory Cytotoxic T Lymphocytes (CTLs) survival and more efficient viral clearance from infected airways. Therefore, genetic variations in the genes coding for IFITM proteins can lead to variability in establishing SARSCoV2 infection in the host.

HOST GENETIC FACTORS RELATED TO SARS-CoV-2 REPLICATION/PROTEIN EXPRESSION FOR REGULATING CORONAVIRUS INFECTION

Glucose Regulated Protein 78 kDa (GRP78)

Glucose regulated protein 78 kDa (GRP78) or immunoglobulin heavy chain binding protein (BiP) localizes to the lumen of the endoplasmic reticulum (ER) and is involved in the folding and assembly of proteins as an ER stress sensor under reasonable conditions. GRP78 is also found on the cell surface as a signal receptor. During cellular stress, elevated expression of GRP78 increases the chance for GRP78 to escape ER retention and translocate

to the cell membrane. Cell surface GRP78 (csGRP78) triggers various downstream cell signaling pathways by interacting with its ligands. Various pro-proliferative, pro-survival ligands, and pro-apoptotic ligands have been discovered. Furthermore, there is evidence that the substrate-binding site of csGRP78 is susceptible to virus recognition and it can be mediate the virus entry into the host cell [27]. Chu et al. (2018) published that GRP78 is capable of facilitating surface attachment of MERS-CoV spike protein. An *insilico* study suggests the existence of a SARSCoV-2 spike protein-GRP78 binding site. However, it is not yet known whether the expression of GRP78 and its polymorphisms have a role in determining the susceptibility and resistance to coronaviruses.

Cyclophilins

Cyclophilins (CyPA), a subgroup of the large immunophilins protein family, are peptidyl-prolyl isomerases involved in the folding of cellular proteins and cell signaling. They play a pivotal role in the replication of several RNA viruses, including nidoviruses (arteriviruses and coronaviruses), and are necessary for proper viral propagation. Cyclophilin A (CypA) and B have been shown to interact with non-structural protein 1 (nsp1) of SARS-CoV intracellularly [29]. Therefore, cyclophilins and its overexpression are significant in the pathogenesis of viral infection. It has been reported that SNP variants causing amino acid exchanges around enzymatic peptidyl-prolyl cis/trans isomerase in CypA may directly affect the propagation of HCoV-229E [30]. Although polymorphisms in the CypA gene have also been documented to influence susceptibility to HIV-1 infection, whether these variations play a role in COVID-19 susceptibility and progression remains largely undocumented.

HOST GENETIC FACTORS IN THE IMMUNE RESPONSE TO SARS-CoV-2

HLA Loci

Classical human leukocyte antigen (HLA) molecules encoded by MHC genes are a specific group of molecules expressed on the cell surface. They are crucial for the recognition of non-self molecules by the acquired immune system. MHC molecules acting as a receptor for viral peptides present the peptides to the virus-specific cytotoxic CD8⁺ T lymphocytes. These cells recognize the conformational structure of the peptide-binding groove of the MHC class I molecules, bound to viral peptides. Variations within MHC class I genes determine both variation in the conformational structure of the peptide-binding groove and its binding to varied antigen peptides. Therefore, it is generally accepted that HLA genes are critical in the immune response against pathogens and more authors consider them as the leading candidates in conferring susceptibility to infectious diseases. MHC classical class I and class II genes exhibit many variants (alleles) and have several thousand reported polymorphisms. Several genetic variants at HLA genes have been identified that account for inter-individual differences to the immune response against common viruses. Accumulating evidence suggests that genetic variability in the HLA-A, -B, and -C genes may also affect susceptibility

to and severity of the disease caused by SARS-CoV-2 [31]. However, whether distinct HLA allele distribution in various populations provide distinct protection or vulnerability to COVID-19 is unclear.

A Genome-Wide Association Study (GWAS) demonstrated that HLA may act as a susceptibility factor for several common infectious diseases [32]. Several studies on SARS-CoV-1 reported higher risk allele frequency of HLA-B*46:01, HLA-B*07:03, HLA-C*08:01, and HLA-DRB1*12:02 and the increased protective allele frequency of HLA-DRB1*03:01, HLA-C*15:02, and HLA-DRB1*03:01. Contrary to this, some studies have been inconsistent and conflicting. On the other hand, *in silico* studies predicted that HLA-B*15:03, HLA-A*02:03 and HLA-A*31:01; and HLA-A*02:01 as effective antigen presenters for SARS-CoV-2, implying that these would provide protection, while HLA-A*03:02 and HLA-B*46:01 had fewest predicted binding peptides for the virus, implying that these would increase susceptibility to COVID-19 [31, 33, 34]. These studies also suggested that HLA-A*02:02, HLA-B*15:03, HLA-C*12:03 haplotypes exhibited the highest and HLA-A*25:01, HLA-B*46:01, HLA-C*01:02 haplotypes displayed the lowest predicted repertoire of epitopes from SARS-CoV-2. Based on bioinformatic prediction and molecular modeling studies with reporting positive findings, HLA molecules could be considered as a genetic gateway for SARS-CoV-2 infection.

Taking into account spatial variation of COVID-19 positive cases, it is becoming increasingly apparent that population-specific HLA alleles or haplotypes could act as a critical intrinsic determinant of protective immunity against SARS-CoV-2 and make population groups and some individuals resistant or susceptible to COVID-19 infection. Results from the studies investigating the geographical pattern in COVID-19, the risk of virus infection, and its clinical outcome in African and Indian populations have been comparatively less than European and other world populations. Based on their comprehensive *in silico* analyses, HLA-A*02 subtypes that are predicted to be protective exhibit higher frequency in Indian and several African populations, which are comparatively less than among populations for the risk and severity of COVID-19. HLA-C*12:03 as the susceptibility allele appears to be the most frequent in the European population. However, whether distinct HLA allele distribution in various populations confers protection or vulnerability to COVID-19 is a topic of debate and discussion.

Inflammatory Factors and IL-6

Cytokine storm and then an exacerbated inflammatory response have been proposed as the basis of the pathophysiological process of SARS-CoV-2 infection. The severity of the disease has been demonstrated to be correlated with high serum levels of IL-2 receptor (IL-2R) and IL-6 (≥ 80 pg/mL) in patients with COVID-19.

Variations in the production and activity of cytokines are associated with SNPs in various regions of cytokine genes, such as IL12RB1 and IFN- γ +874A allele, and influence the susceptibility and/or resistance to various infectious pathogens. It is now well-established that ethnicity greatly influences cytokine gene polymorphism distribution. Although there is evidence supporting the associations between several cytokine gene polymorphisms and SARS-CoV, there are no studies on the impact of cytokine gene polymorphisms on the risk of

SARS-CoV-2. But, taking into account a critical role of cytokines in influencing the severity of COVID-19 and an important role of genetic background in determining the pattern of the inflammatory response, allelic variations in cytokine genes look like to play an underlying role in COVID-19.

Some Other Possible Candidate Immune Genes to COVID-19 Susceptibility

As known, there are various upstream regulators, such as the Toll-like receptor (TLR) involved in the control of cytokine expression. Additionally, components of the innate immune system such as complement components have also close interactions for cytokine responses. Therefore, host genetic factors concerning these components may affect disease susceptibility and pathogenesis.

Few other genetic factors in the immune response to SARSCoV-2 about these components were suggested or reported. One of them is *Ticam2*, codes for an adaptor protein in the activation of the TLR signaling pathways. A mice study revealed that allelic variation in the *Ticam2* influences susceptibility to SARS-CoV infection [35]. Also, researchers demonstrated that *TRIF* which is another adaptor protein of TLR signaling pathways, required for initiating the innate immune response to severe SARS-CoV infection and it protects mice from coronavirus infection [36]. Although, there are no studies on the role of the TLR pathway in SARS-CoV-2 infection, given the genetic variation within the TLR genes or components of the TLR pathway and its distinct distribution pattern in various ethnic populations, the genes involved in TLR signaling could emerge as a major host determinant of differential susceptibility to SARS-CoV-2 infection and severity. However, this assumption needs to be tested empirically for SARS-CoV-2.

TLR pathway genes reported concerning COVID 19 susceptibility or outcome are also discussed in Section “sex chromosomes and COVID-19”.

The complement system efficiently recognizes and eliminates viral pathogens by opsonizing viruses and virus-infected cells. Some writers note that coronaviruses activate multiple complement pathways; There are *in vitro* and *in vivo* evidence indicating that complement activation plays a critical role in pathogenesis and disease progression of SARS-CoV and SARS-CoV-2. For example, a recent study demonstrated that highly pathogenic N proteins of SARS-CoV, MERS-CoV, and SARS-CoV-2 aggravated inflammatory lung injury by aberrant complement activation [37]. Considering that polymorphisms of complement genes are associated with the risk of various infectious diseases as well as various diseases, perhaps complement gene variations in ethnic populations modulate the risk and severity of SARS-CoV-2 infection.

EPIGENETIC MODIFICATIONS AND COVID 19

Epigenetic changes that regulate chromatin structure have a major impact on genome stabilization and maintenance of cellular homeostasis. They have been implicated in the pathophysiology of the virus infection. The epigenetic regulation of gene expression relies on post-translational chemical changes. These changes occur at the level of chromatin as well as

on RNA and DNA, are including primary methylation, but also acetylation, phosphorylation, ubiquitination, and sumoylation. These modifications bridge between genotype and phenotype by changing the function of the gene locus without changing the DNA sequence. DNA methylation is the inheritable epigenetic process by which methyl groups are added to the C-5 position of the cytosine ring of DNA by DNA methyltransferases (DNMTs). In addition, more than 98% of DNA methylation occurs in a CpG dinucleotide context in somatic cells, while as much as a quarter of all methylation appears in a non-CpG context in embryonic stem cells (ESCs). DNA methylation is erased during zygote formation and then reestablished in the embryo at approximately the time of implantation. Most DNA methylation is essential for cell development, and it plays a key role in several processes including the packing of DNA in the nucleus genomic imprinting, X-chromosome inactivation, and suppression of repetitive element transcription and transposition and, when dysregulated, causes to diseases like cancer. DNA methylation is regulated by a family of DNMTs. These family members have been determined as DNMT1, DNMT2, DNMT3A, DNMT3B, and DNMT3L [38]. In recent years, 110 types of RNA nucleotide modifications have been reported, spanning RNA types including messenger RNA (mRNA), transfer RNA (tRNA), ribosomal RNA (rRNA), transfer-messenger RNA (tmRNA), small nuclear RNA (snRNA), and chromosomal RNA, many of which are currently well cataloged at the RNA Modification Database (<http://mods.rna.albany.edu/mods>). RNA modifications not only mark and regulate mentioned these transcripts but also diversify and extend the protein's functionality from the annotated genes [40]. Recent work in this area showed that chemical modifications at the RNA level play a role in gene transcription, translational efficiency, and RNA stability [41]. These modifications of coding and non-coding RNA are including, adenosine methylations, cytosine modifications, isomerization of uridine, and ribose modification [42]. Mass Spec technologies have discovered a series of RNA modifications that are not only non-coding RNAs, including tRNA) and rRNA but are also commonly found within functional mRNAs. Thus, some of the mapped modifications showed dynamic patterns and tissue-specific distribution explaining to the new field of RNA-epigenetics or epitranscriptomics domains. Transcriptomic and epitranscriptomic analyses have primary importance in the study of viruses by determining their structure and function. So, it is provided important information about host infection [41]. Likewise, new data from the Centre for RNA Research and their collaborators at the Korean National Institute of Health (KNHI) within the Korea Centers for Disease Control and Prevention (KCDC) have presented a high-resolution map of SARS-CoV-2. As known, each RNA viral transcript has 5'-cap structure and a 3' poly(A) tail. Nanopore-based direct RNA sequencing was observed motif being the AAGAA present throughout the viral genome. The poly(A) tail plays an important role in RNA turnover and this internal modification may contribute to viral RNA stability and translation efficiency. When the virus enters the host cell, it replicates a genomic RNA that consists of nine open reading frames (ORFs). Thus, the genomic RNA is translated to produce proteins. There are nine subgenomic RNAs transcribed from the genomic RNA. They are encoding conserved structural proteins, namely, the spike protein (S), an envelope protein (E), membrane protein (M), and nucleocapsid protein (N) that synthesize the viral particle [41, 43]. Generally, the virus entering point at the host cell is the ACE2 type I membrane receptor. These receptors are present in arterial and venous endothelial cells, lung type II alveolar cells, enterocytes of the small intestine, and arterial smooth muscle cells in the cerebral cortex and brainstem. According to obtained the data, during SARS-CoV-2 enters

into cells, it is using the receptor-binding domain (RBD) of the spike (S1) protein that contains a core structure and a receptor-binding motif (RBM) to bind the outer surface of the receptor.

Previous studies have shown a strong association between SARS- Cov infection and ACE2 expression levels. Also, a series of comorbidities have been reported in patients who died of COVID-19 infection, including chronic diseases. As known, the *ACE2* gene is located on the X chromosome and is closely related to XCI [41]. XCI is an epigenetic regulation and explained in more detail above. Zyllicz et al. mapped the X chromosome inactivation in several human tissues. Male and female differences were investigated in the expression of X-chromosomal protein-coding and long non-coding RNA (lncRNA) genes and single-cell transcriptomes, along with genomics in Genotype Tissue Expression (GTEx) project. It was detected that although XCI is essentially uniform across human tissues, some heterogeneity can also occur between cells, tissues, and individuals. The data have shown that escaper genes were caused to result in sex biases in gene expression and so in phenotypic diversity. *ACE2* was found among one of these genes in female lung tissue, showing a more heterogeneous sex bias. Moreover, *ACE2* expression was slightly higher in males than in female tissues. This condition may be the reason for higher respiratory infection severity in male than in female patients [9, 44]. Recently research studies in the regulation of the *ACE2* gene by DNA methylation indicated that the host epigenome may represent a risk factor for COVID-19 infection [41]. Moreover, age-dependent DNA methylation was detected close to the transcription start site of the *ACE2* gene by the techniques of DNA methylation analysis in airway epithelial cells. Corley et al. using Illumina DNA methylation sequence data from samples of different biological ages, they found that a CpG near the *ACE2* transcription start site showed a decreased level of methylation during aging. Previous studies had suggested that DNA methylation levels are reduced during aging. Thus, differential methylation patterns of genes involved in inflammation, aging, and immunity response were obtained. These data could explain the higher morbidity rates of the virus infection in older individuals and patients with underlying medical conditions [45]. Additionally, the *ACE2* promoter has been found hypomethylated in endometrial carcinoma and renal papillary cell carcinoma tissues. Thus, *ACE2* expression levels increase in these patients. When these patients were affected by SARS-CoV-2, their prognosis may worsen [46].

It was reported that epigenomic alterations play a basic role in distinguishing immune cell phenotypes and regulating inflammatory responses to intrinsic or extrinsic stressors with aging. Specific epigenetic modifications such as histone acetylation/ methylation in chromatin play essential roles in response to viral infection. Epigenomic patterns of aging result in decreases in naive T cells and increases in monocytes and cytotoxic cell functions. Whereas, the size of alterations is more significant in men than in women, with an accompanied loci specific methylation decline in the B cells. Thus, it is thought that gender and age differences in epigenetic patterns of immune cells may partially explain the diversity in the severity of COVID-19. However, the epigenetic changes in CpG-sites located in subtelomeric regions which control innate immunity can mediate inflammatory responses to COVID-19 [47].

Epigenetic and Possible Treatment/Vaccine Options for SARS-CoV-2

As is known, the epigenetic regulation of multiple genes can be intervened by natural factors and named as epi-drug. Inhibition of *ACE2* and furin expression with the use of drugs such as vitamin D and quercetin for the treatment of SARS CoV-2 is recommended [48]. Other candidate epi-drugs for epigenetic silencing of *ACE2* and interferon genes are curcumin, deferasirox, 8-hydroxyquinolones (8HQ), and sulforaphane (from broccoli) [49 - 51]. It is suggested that all of these substances are natural medicines and could help to reduce disease severity and susceptibility. Ferritin values in severe SARS-CoV-2 patients increase and accordingly their clinical results worsen [48]. Curcumin is especially important as it has ferritin-lowering effects [52].

TELOMERE LENGTH AND COVID 19

Telomeres are repetitive nucleotides (TTAGGG)_n at the ends of each chromosome. They play a role in maintaining genome stability and regulate immunity in response to viral infection. Subtelomere regions contain CG-enriched genes that regulate immunity. These genes are influenced by telomere length and regulate telomere repeat-containing RNA (TERRA) transcription. Their expression can be upregulated in response to viral infection by activation of interferon-stimulated genes. Thus, telomere shortening, coupled with dysregulated innate and adaptive immune responses to viral infection, can cause severe outcomes in older adults with COVID-19 [47, 53]. Earlier studies reported that telomeres play a major role in influencing the process of cellular senescence and can be associated with maintaining lung health. In addition, telomere dysfunction was also associated with smoking and chronic obstructive pulmonary disease [54 - 56]. Some agents in smoke may activate DNA damage response by influencing telomere function and the level of CD4⁺ and CD8⁺ T cells significantly is reduced. Furthermore, viral replication activates interferon regulatory factors (IRFs) and TLR-3-induced NF- κ B pathway; which towards the increase in the production of proinflammatory cytokines and cytokine storm. There is evidence that the NK cells are significantly increased in older adults while the percentages of type T of cells decreased. In aged individuals, APCs secretion of pro-inflammatory cytokines increased while they secrete reduced levels of anti-inflammatory and immune-regulatory cytokines. One of the especially differences at the DNA level between old age persons and children is their telomere length. The immune system is extremely sensitive to the shortening of telomeres. Because the immune system depends on cell renewal and clonal expansion of T and B types of cells [57]. Lymphopenia which a decline in the number and exhaustion of T lymphocytes characterizes severe acute respiratory syndrome by betacoronaviruses. It is thought that the short leukocyte telomere length (LTL) may partially explain the lymphopenia associated with COVID-19. As known, within every person, hematopoietic cells show age-dependent telomere shortening. Lymphopoiesis is linked to telomere length and telomerase, whose activity varies in different lymphocyte lineages [58]. There is a marked variation in LTL between humans. This difference is dependent on the effects of gender, paternal age at conception, and environmental exposures. Various research showed that short LTL was associated with a high risk of hospitalization due to pneumonia and a significant risk of death

related to infections. Another study on immunity after flu vaccination documented that, individuals with long telomere length in B-lymphocytes produced a more strong antibody response when compared to individuals with short B-lymphocyte telomere length [57]. According to authors, inter-individual differences in telomere length and the concomitant propensity of T cells to undergo senescence due to aging might play a critical role in severe lymphopenia associated with COVID-19 and its often fatal outcome. Older people and those with pre-existing conditions are very much affected by COVID-19 and are more susceptible to poor clinical prognosis. The aging-related decreases in NAD⁺ with a reduction in telomeres length negatively influence the immune response and COVID-19 outcome. In addition, the use of NAD⁺ as an immunomodulator in older patients with COVID-19 could decrease the severity of immune reaction in those patients and improve their clinical condition [57, 58].

RELATIONSHIP BETWEEN ABO BLOOD GROUP DISTRIBUTION AND COVID-19

The ABO blood group consists of two antigens (A and B antigens), which are the ABO gene product and includes 4 blood types, namely, A, AB, B, and O. Blood typing are performed as ABO, Rh with standard antibody-based methods. Blood group antigens present at least 300,1 on red blood cells (RBCs), since the discovery of the ABO system [59, 60]. The human ABO blood group is located on chromosome 9 (9q34.1–34.2) [61]. Many studies have reported that the ABO blood group plays an important role in various human diseases, such as cardiovascular, oncological, and some infectious and non-infectious diseases. Human histo-blood group antigens (HBGAs) are some of the important antigens on the surface of human red blood cells. These antigens are highly expressed in a wide variety of cells and tissues, including epithelia, platelets, vascular endothelia, and neurons, and also important as receptors for immune responses. The ABO blood types have polymorphic traits within the ABO gene, and blood types have considerably different distributions across ancestry groups. Differences in blood group antigen expression can affect a different level to host susceptibility to many infections. A series of studies shown that the ABO blood group has been previously found to relate to the risk of multiple infectious diseases such as hepatitis B, malaria, rota, dengue viruses, and SARS coronavirus. Furthermore, many blood group antigens have the effect of facilitating intracellular uptake, signal transduction, or cell adhesion through the organization of membrane micro-domains. Blood group antigens can modify the innate immune response to infection [61 - 65]. In addition, an association was shown between variants within ABO and activity of ACE which modulating sensitivity to SARS-COV 2 by genome-wide association studies. The numerous association studies between blood type and COVID-19 present reasons to believe true associations may exist between blood type with morbidity and mortality due to COVID-19 [64]. In recent data, the results of studies demonstrated that there was a significant association between the A blood group and COVID-19. They reported that females with blood type A are more susceptible to COVID-19 infection [60, 63]. Similarly, Li et al., determined that the rate of patients with SARS-CoV-2-infected A blood group was significantly higher than healthy controls, while the proportion of patients with SARS-CoV-2-infected O blood group was lower. Also, they

suggested that blood group A patients were at higher risk of hospitalization than blood group O patients following SARS-CoV-2 infection [66]. As known, blood type O individual expresses the H antigen, the biosynthetic precursor to A and B antigens. In addition to red blood cells, numerous tissues and secretions such as the endothelium, intestinal mucosa, heart, kidney, and other organs express ABH antigens. This antigen is a carbohydrate antigen and expressed on glycoproteins and glycosphingolipids (GSLs). Earlier, glycan analysis of SARSCoV S protein shown that SARSCoV S protein has a broad range of structures, such as complex Nglycans with 2–4 antennae able to support ABH epitopes. This is highly probable for the virus targeted to respiratory and gastrointestinal mucosa [60]. Several different study groups, reported a possible association between blood type A and a higher risk for COVID-19 infection and mortality while blood group O was associated with a lower risk of infection and mortality. However, there is still a lack of data on the relationship between ABO blood typing and the severity of COVID-19 disease [64, 67, 68]. There are also opinions against these data. For example, Latz et al. performed a study using a large multi-institutional cohort of patients. According to this study, there was no association noted between ABO blood type and COVID-19 disease severity defined as intubation or death, but blood type O had the lowest frequency of disease positivity, similar to other groups [62]. Conversely, Ellinghaus et al. suggested that there is also a lower probability of intubation for all non-O blood types [68].

Cheng et al. suggested that patients with blood group O had decreased susceptibility to SARS-CoV infection [69]. It has been reported that anti-A antibodies found in individuals with blood group O might block the interaction between SARS-CoV and its receptor, thus protecting against SARS-CoV infection. Based on these results, it can be speculated that the susceptibility to COVID 19 decreased in individuals with blood type O, while increased in individuals with blood type A may be related to the presence of anti-A antibody in the blood. Because anti-A antibodies can block the interaction between the virus and its receptor. This condition may explain why blood group A is sensitive to the virus while blood group O is not. In addition, Wu et al. indicated that blood type might have some influence on the clinical characteristics of patients with COVID-19 in their study. They observed that the clinical features of people with different blood types after infection with COVID-19 were different. As a result, it is thought that the blood type of individuals may not be one of the risk factors for COVID-19, but may be related to the clinical characteristics of COVID-19 patients [61, 70].

There is also evidence for the relationship between Rh type and very few diseases compared to ABO. Similarly, Rh(D) phenotypes (positive and negative Rh blood types) are important for immune response. Zietz et al. found that there were greater risk differences between Rh blood than between ABO strains, and in particular Rh-negative individuals had a lower risk [62, 64].

CONCLUSION

Some human genetic variants have previously been identified that influence susceptibility or resistance to infection with various virus pathogens. Even though many questions remain unresolved, there is also a growing consensus among the scientific community that some

Table 1. Host genetic factors related to COVID-19 disease reported from previous studies as protective and permissive genes

Gene(s) or Locus	Genetic variation/alteration	Effect of genetic alteration	Association/ Possible mechanism (s) -process influenced by host genetic factor/variation	Ref (s)
ACE2	Escaping from XCI Epigenetic modifications SNPs: rs73635825 rs143936283	Two dose expressed in females Hypomethylation during aging	Excessive Immune response Susceptibility to infections Protection/ low binding affinity with SARS-CoV-2 spike protein	[4, 10, 11] [9, 41, 44, 45] [20]
TMPRSS2 IFTM3	eQTL rs34481144	Increased expression of TMPRSS2	Different susceptibility or response to SARS-CoV-2 Protection/increased memory CTLs survival and more efficient viral clearance	[24] [26]
TLRs HLA	Escaping from XCI HLA-B*15:03, HLA-A*02:03 and A*31:01; and HLA-A:02:01 <i>Haplotype</i> : HLA-A*02:02, HLA-B*15:03, HLA-C*12:03 HLA-A*03:02 and HLA-B*46:01 <i>Haplotype</i> : HLA-A*25:01, HLA-B*46:01, HLA-C*01:02	Two dose expressed in females	Protection/relatively reduced antiviral immunity Protection/ effective antigen presentation for SARS-CoV-2	[4, 11, 12] [31, 33, 34].
CG-enriched genes in sub telomere which are regulated TERRA transcription	Short telomere length		Susceptibility/ fewest predicted binding peptides for virus- increased susceptibility to COVID-19	
The ABO blood group	Blood type O		Susceptibility dysregulated innate and adaptive immune responses/Lymphopenia -T lymphocytes Protection/ blocking the interaction between the virus and its receptor	[47, 57, 58] [61, 69, 70]

genetic variants in genomes of individuals might confer differential susceptibility and influence the severity and progression of SARS-CoV-2 infection, as well as age, biological sex, and major comorbidity factors such as cardiovascular disease and metabolic disorders. Taking into account the general findings in the literature (Table 1), we discussed the expression level or mutation and variation in some host genetic factors such as ACE2, TMPRSS2, GRP78, TLR7, HLA, ABO blood group, as well as epigenetic changes regulating host response and inter-individual variation in leukocyte telomere length. Many of these host genetic factors also exhibit population-specific variation and is associated with susceptibility and/or resistance to various viral diseases.

There are multiple limitations to our summaries for each identified genetic variations concerning COVID-19 susceptibility. Firstly, the studies and information on SARS-CoV-2 infection continue to increase very rapidly since its emergence. Therefore, we can't cover them all here. Secondly, some studies that have been conducted may not have reported relevant data because of publication biases. Thirdly, most studies, including a large patient population, were conducted in China, and the study of asymptomatic carriers was limited. Lastly, the potential impact of previous exposure to other coronavirus species in influencing population discrepancy and severity of SARS-CoV-2 is also uncertain. Moreover, it should be kept in mind that the large majority of studies reporting positive findings may be affected by a strong risk of bias or confounding. More research findings with a larger dataset are needed to help to understand the role of gene networks in determining or influencing the efficiency of infection and progression of COVID-19.

Chapter 460

THE CLINICAL COURSE OF COVID-19 IN ELDERLY PATIENTS

Hakan Yavuzer*, MD and Rabia Bag Soytas, MD

Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty,
Department of Internal Medicine, Division of Geriatrics,
Istanbul, Turkey

ABSTRACT

COVID-19 disease, which affects the whole world and is declared as a pandemic by the world health organization, affects the elderly mostly due to both physiological changes because of aging and its comorbidities. Studies have reported that mortality and morbidity are higher in the elderly than young people. Like other infections, COVID-19 disease can manifest itself with different symptoms, as the immune response decreases with aging. Also, they have difficulties in describing and expressing the symptoms because of the decrease in their cognitive functions, which leads to a delay in hospital admissions. Although there are no findings specific to the elderly in laboratory values and radiological imaging, some findings were found to be more common in the elderly. Among the treatment options, a different treatment protocol specific to the elderly is not applied. However, since the comorbidities of geriatric patients and the number of medicine they use are high, care should be taken in terms of medicine side effects and drug-drug interactions during treatment. The COVID-19 epidemic affects the elderly not only physically, but also socially and psychologically. All these situations lead to a more severe course of COVID-19 disease by causing increased malnutrition and sarcopenia in the elderly and making them frailer. During the COVID-19 pandemic process, elderly patients should be evaluated considering all these conditions and necessary medical, psychological, and social support should be provided.

INTRODUCTION

The Coronavirus disease 2019 (COVID-19) outbreak, which occurred due to the new coronavirus (SARS-CoV-2) and spread rapidly all over the world, was declared as a pandemic by the World Health Organization (WHO) on March 11, 2020 [1]. The pathogen has been identified as a novel enveloped RNA beta-coronavirus called acute respiratory syndrome coronavirus 2 (SARS-Cov-2). It can cause a wide range of diseases ranging from mild illness like flu to critical illness such as sepsis, multiple organ failure, and severe respiratory failure. The disease is transmitted from person to person by droplets and by touching mouth, nose, and eye mucosa with dirty hands after touching surfaces containing viruses. Symptoms of the disease; the first symptoms appear within an average of 5-6 days (may extend from 2-14 days) after the virus enters the body [2].

The elderly population in the world is gradually increasing. While the population aged 65 and over was 6% in 1990, it increased to 9% in 2019. In 2050, it is expected to be 16% [3]. It is known that patients over the age of 65 are frailer due to comorbidities and age-related physiological changes and they are more affected by many diseases than young people [4]. It has been reported that the majority of those who were hospitalized and died among patients infected with COVID-19 consisted of elderly patients causing higher mortality rates, especially in the elderly with cardiovascular disease, chronic respiratory disease, diabetes, or another health problem such as cancer [5]. The Centers for Disease Control and Prevention (CDC) reported that 17% of the total population in the United States is over 65 years. However, 65 years and older patients were responsible for 31% of COVID-19 infections, 45% of hospitalizations, 53% of intensive care unit admissions, and 80% of deaths caused by COVID-19 [6]. Also, many studies have shown that mortality increases with an increasing age [7]. In a study with 72,314 cases, it was shown that the overall mortality rate was 2.3% but increased to 8% between the ages of 70-79 and 14.5% in patients over 80 years old [5]. Therefore, it is important to know the clinical, laboratory, and radiological characteristics and treatment options of elderly patients infected with COVID-19.

CLINICAL CHARACTERISTICS

Older individuals are more prone to infections due to multiple chronic diseases, weak immune systems and their recovery are slower than younger people. As a result of natural changes that occur in the body with aging, the symptoms and clinical course of COVID-19 may be different from young individuals.

According to the CDC, 63.1% of adults aged 60 and older have hypertension, 38% of people aged 65 and older have chronic kidney disease (CKD), and 26.8% of adults aged 65 and older have diabetes [8-10]. In a study in which 312 patients infected with COVID-19 aged 65 and older were included, 77.2% of the patients were reported to have comorbidity. Like the general population, the most common comorbidity in these patients (57.1%) was hypertension, followed by diabetes mellitus (38.8%), cardiovascular disease (29.8%), chronic lung disease (8.65%), cerebrovascular disease (6.4%) [11]. In another study, 69.5% of geriatric patients had comorbidity, and the most common comorbidities included hypertension (43.8%), diabetes (25.7%), and cardiac disease (16.2%) [12]. Older patients

with comorbidities were more likely to progress to severe disease [13]. Therefore, it is vital to know and control chronic diseases in elderly patients with COVID-19. For example, when we consider the most common comorbidities, it is very important to keep blood pressure and glucose under control.

The risk and severity of developing an infection depend on the relationship between the pathogen's virulence, its inoculum, and the host's defense system. Virulence of a pathogen is determined by the ability to attach and replicate in a host environment. With the physiological changes brought about by aging, macrophage function changes, mucocutaneous defenses are compromised, cytokine production decreases, and T cell function is insufficient. Comorbid conditions such as diabetes, congestive heart failure, kidney failure, chronic lung disease, and malnutrition deteriorate the immune system. For these reasons, infections may show an atypical course in geriatric patients. Current data show that COVID-19 infections may also start with atypical presentations in a significant portion of the elderly [14]. Geriatric patients with COVID-19 may only have fatigue, myalgia, headache, or vomiting without fever or cough. It should be kept in mind that this situation may cause patients to apply to the hospital later, to be diagnosed later, and to start treatment later, and therefore to be more fatal. For example, traditionally, fever is defined as the body temperature above 38°C, but one-third of the elderly with acute infection usually does not have a fever at these values. A previous report noted that fever may be reduced or even absent in elderly patients with bacterial or viral infections due to low basal temperature, impaired thermal homeostasis due to aging, and frequently-used medicine such as aspirin [15]. In addition, healthy elderly people tend to have lower body temperatures compared to young people. The Infectious Diseases Practice Guidelines Committee of America has defined fever in the elderly as:

1. A single oral temperature > 100°F (37.8°C)
2. Repeated oral temperatures > 99°F (37.2°C) or rectal temperatures > 99.5°F (37.5°C)
3. Temperature increase > 2°F (1.1°C) relative to baseline temperature

The most common symptoms in the general population are fever (98%), cough (76%), shortness of breath (55%), and myalgia or fatigue (up to 44%) [16]. Although these symptoms are the most common in elderly patients, their incidence is different compared to young people. In studies of elderly individuals with COVID-19 infection, the most common symptoms were reported to be shortness of breath (76%), high fever (52%), and cough (48%) [7]. In another study; 66.7% of elderly patients had a fever, 64.8% cough, and 33.3% fatigue on admission. Other symptoms include shortness of breath (29.5%), diarrhea (9.5%), anorexia (8.6%), headache (8.6%), myalgia (7.6%), and vomiting (5.7%). In the same study, the median incubation period in elderly patients was 8 days, and the time from the onset of symptoms to hospitalization was 5 days. The atypical course of the disease in the elderly and the delayed perception of the symptoms due to the decrease in the cognitive functions of the elderly cause late admissions to the hospital. This causes the late initiation of treatment and a more serious and mortal course of the disease.

Cough and shortness of breath symptoms can be misleading in older individuals. The cough reflexes in the elderly are weakened and differential diagnosis should be made well in the elderly who present with dyspnoea due to the prevalence of chronic respiratory failure and heart failure causing dyspnoea. It was observed that the complaints of cough and sputum were

similar among the elderly and young people, while the complaints of shortness of breath were more common in the elderly [17].

In a study in which 214 patients were evaluated, neurological findings were detected in 36.4% of the patients. In this study, neurological symptoms were classified into three categories. CNS symptoms or signs (headache, dizziness, impaired consciousness, ataxia, acute cerebrovascular disorder or epilepsy) were detected in 24.8% patients, neuropathy symptoms (hypogeusia, hyposmia, or neuropathic pain) were detected in 8.9% patients, skeletal muscle symptoms were detected in 10.7% patients [18].

In a review in the literature, the smell changes were reported as 60.7%, and the frequency of taste changes was reported as 56.4% [19]. Fatigue, weakness, headache, and gastrointestinal system findings in elderly patients are similar to those in young people. Along with these, elderly patients may present with confusion and impaired oral intake. In addition, it has been reported that cardiac complications such as myocarditis, pericardial effusion, and arrhythmia can be seen in cases with a severe course of the disease [20]. The pre-diagnosis of COVID-19 infection should be kept in mind in patients presenting with these complaints.

While trying to control the infection in elderly patients, we should also consider the complications we encounter frequently. Delirium is a common complication of infections, especially in older adults. In the first studies, it was shown that 20-30% of COVID-19 patients develop delirium on admission to the hospital or during the disease [21]. In all age groups, this rate has been reported to be 60-70% in those with severe disease. Although the exact cause of this relationship is unknown, it is thought that there may be multiple factors such as direct neurological invasion, cerebrovascular involvement or indirect high fever, hypoxia, dehydration, inflammation, medications, or metabolic disorders.

COVID-19 disease has been reported to increase the risk of thrombotic events, including stroke. In some studies, the incidence of ischaemic stroke in patients infected with COVID-19 is approximately 2.5%. In a study, the rate of hemorrhagic stroke was found to be 0.9%, and it was reported that 88% of these patients were using anticoagulants [22]. Although the mechanisms of cerebrovascular events in COVID-19 have not been clarified, it has been reported that coronavirus directly infects endothelial cells and causes widespread endothelial inflammation in cases with severe respiratory syndrome. This may be a mechanism leading to ischaemic stroke or hemorrhagic stroke.

LABORATORY CHARACTERISTICS

In available studies in the literature, it has been reported that lymphopenia is common in patients with SARS-CoV-2 infection. It has been observed to occur in 32.5-75.4% of COVID-19 patients in different studies [23]. Lymphopenia was also a common finding in severe acute respiratory syndrome coronavirus (SARS CoV) and Middle East respiratory syndrome coronavirus (MERS-CoV). Also, one study reported that severe cases of COVID-19 were reported to have lower lymphocyte count and higher neutrophil count than non-severe cases; therefore Neutrophil/lymphocyte ratio (NLR) tends to be higher in patients with severe infection [24].

Commonly, the studies reported that D-dimer, lactate dehydrogenase (LDH), and C-reactive protein (CRP) levels increased, and albumin level decreased among elderly patients

with COVID-19 [12]. In a study comparing elderly people with middle-aged and younger individuals, it was shown that elderly patients had lower lymphocyte counts and higher CRP levels [25]. CRP is an acute-phase protein produced by the liver that can be elevated in a variety of conditions such as inflammation, cardiovascular disease, and infection. Some studies reported that CRP height is related to COVID-19 mortality [26]. Although D-Dimer is a specific marker of fibrinolysis used to predict venous thromboembolism, it may also increase inflammation and indicate a poor prognosis. As a matter of fact, there are investigations in the literature that show that high D-dimer levels predict COVID-19 mortality [27]. The decreased albumin and increased LDH suggest that SARS-CoV-2 infection is associated with extrapulmonary organ injury, such as hepatic or myocardia injury. In addition, there is reliable evidence that increasing LDH values reflect the degree of pulmonary damage in Acute Respiratory Distress Syndrome (ARDS) patients [28]. High procalcitonin levels have been reported in moderate-to-severe cases [29]. In a meta-analysis, it was reported that troponin, CK-MB, and NT-proBNP were significantly higher in severe COVID-19 cases than in mild cases and mortality was higher in patients with acute cardiac injury [30].

Ferritin is a protein that contributes to cytokine storm with its immunosuppressive and proinflammatory effects. In some studies, it has been reported that the ferritin level correlates with the severity of the COVID-19 disease [31]. Publications are showing that it predicts mortality. Therefore, it may be important to check the ferritin level on admission to the hospital and follow-up of the disease ints, including elderly patients, to be more controlled against the disease.

Especially in elderly patients with COVID-19, it is important to monitor the course of the disease and its response to treatment with laboratory tests, as patients may have difficulty in identifying symptoms and the disease may be atypical.

RADIOLOGICAL CHARACTERISTICS

The most important involvement site of Coronavirus Disease 2019 (COVID-19) is the lung [32]. Therefore, it is very important to demonstrate lung involvement radiologically. Although the gold standard in the diagnosis of the disease is the Real-Time Polymerase Chain Reaction (RT-PCR) test, radiological imaging has started to be used extensively due to the inadequacy of the test in some places and its early false-negative results [33]. However, radiological methods are not screening tests in the diagnosis of COVID-19; It should not be forgotten that it should be used as a method to help diagnose and monitor the disease. In imaging, chest radiography, thoracic computed tomography (CT), and in some limited centers, thoracic ultrasonography (US) is used for this purpose. Chest radiography is the first-choice imaging method for demonstrating COVID-19 pneumonia. However, it should be kept in mind that the limited ground-glass opacification (GGO) in the lungs, especially in the early phase of the disease, cannot be seen on radiography. The sensitivity of chest radiography in demonstrating disease involvement has been reported to be 30-60% [34]. Typical findings on CT related to COVID-19 pneumonia are GGO, flagstone appearance, consolidation, air bronchogram, vascular enlargement, bronchial dilatation, halo sign, inverted halo sign, nodules, air-bubble sign, subpleural - parenchymal bands, and pleural changes [35]. In a study

evaluating 919 COVID-19 patients, it was found that 88% of patients had ground-glass opacification (GGO), 87.5% had bilateral involvement, 76% had peripheral distribution, and 78.8% had multilobar involvement. Isolated GGO or GGO and consolidations were found to be the most common CT findings [36]. In the studies comparing the elderly and middle-aged groups, it was observed that multilobar and widespread involvement were more common in elderly individuals [27]. In the chest imaging of older adults; bilateral reticular-nodular opacities (58%), GGOs (48%), pleural effusions (about 33%), peribronchial thickening (about 25%), and focal consolidations (20%) have been reported [37].

TREATMENT

There is currently no specific treatment for COVID-19 infection with proven efficacy. Over 100 randomized controlled trials are being conducted for effective treatment trials against COVID-19. Since there is no treatment specific to COVID-19, medicines such as hydroxychloroquine, favipiravir, remdesivir, lopinavir-ritonavir, which were licensed for the treatment of other diseases in humans before, has been recommended and used during the current pandemic in our country and other countries. Numerous studies are still going on for the effectiveness and safety of these medicines in COVID-19. There is no difference between elderly patients and younger patients in terms of treatment options.

Chloroquine (CQ) and hydroxychloroquine (HCQ) have been used for more than 70 years to treat malaria and some autoimmune diseases. These medicines have become the candidate medicines for the treatment of COVID-19 infection because of their immunomodulatory effects and the effects that prevent viruses from entering the cell. It has been reported that at the beginning of the pandemic process, the use of CQ shortens the duration of the disease and slows its progression [38]. In addition, there are studies in the literature that suggest the use of HCQ reduces viral load in COVID-19 infection [39]. There are also studies on the negative effects of CQ and HCQ treatment. Despite their conflicting results, CQ and HCQ are included in COVID-19 treatment guidelines around the world. HCQ therapy is known to prolong the QT interval. Risk factors for QT prolongation include advanced age, female gender, history of heart disease, hypokalaemia, the use of furosemide and thiazide diuretics, kidney and liver failure, and the use of other medicines that prolong the QT interval. Elderly individuals are particularly at risk for QT prolongation and Torsades de Pointes. There is a risk of QT prolongation due to the high risk of hypertension in many elderly people, history of using antihypertensive medicines combined with diuretics, concomitant heart failure, polypharmacy, and inappropriate medicine use, and care should be taken in the use of HCQ in these patients. In patients without risk, the corrected QT (QTc) should be calculated by taking a basal electrocardiogram (ECG) before starting the medicine. If basal QTc is > 500 ms, HCQ therapy should be avoided. If the QTc length is normal, treatment is started and daily ECG monitoring is recommended [40]. Care should be taken in this regard especially in elderly patients, and they should be evaluated in detail regarding drug interactions during the treatment of COVID-19 infection. In addition, the combined use of azithromycin-HCQ, which was previously included in the guideline, is no longer recommended due to the high number of side effects.

It has been shown in animal studies and in vitro studies that Lopinavir inhibits the protease activity of coronaviruses. Additionally, in SARS and MERS outbreaks, lopinavir/ritonavir treatment is effective and reduces mortality, so it has been a candidate medicine for COVID-19 treatment [41]. In a lopinavir/ritonavir versus arbidol comparative study of individuals with mild to moderate COVID-19 infection, no significant difference was found between treatments [42]. In severe cases of COVID-19, the addition of lopinavir/ritonavir therapy to standard therapy has been reported to provide no additional benefit in terms of clinical improvement but rather increase the frequency of side effects [43]. The results of other studies in the literature were similar. In summary, lopinavir/ritonavir monotherapy or combination therapy has not been shown to contribute to the standard therapy.

Remdesivir, which has a broad antiviral activity and works by targeting viral RNA-dependent RNA polymerase (RdRp), has also been shown to be effective against coronaviruses [44]. In a randomized study involving 1059 patients (538 assigned to remdesivir and 521 assigned to placebo), it was shown that the mean recovery time for those who used the placebo was 15 days while it was 11 days for those who used remdesivir. In addition, remdesivir was found to be sufficiently tolerated and safe. It was found that serious side effects were lower in those who used remdesivir compared to those using a placebo. However, adverse events such as gastrointestinal symptoms (anorexia, nausea, and vomiting), increased liver enzymes, and worsening of cardiopulmonary status were seen at a higher rate in remdesivir users than in placebo users [45]. There is no different data on the use of remdesivir in the elderly.

Favipiravir acts by inhibiting RNA-dependent RNA polymerase. Vitro studies have shown that favipiravir is effective against coronaviruses. In a study of 120 patients with mild to moderate infections, when favipiravir and arbidol therapies were compared, clinical improvement at day 7 was better in patients using favipiravir [46]. In another study, favipiravir and lopinavir/ritonavir treatments were compared; it has been shown that viral clearance is faster (4 vs 11 days) and radiological lung recovery is better (91% vs 62% in 14 days) using favipiravir [47].

In patients with severe COVID-19 pneumonia, macrophage activation syndrome (MAS) and secondary lymphocytic lymphohistiocytosis may develop due to excessive hyperstokemia (IL-1, IL-6, IFN-gamma, etc.). In the MAS table of COVID-19 patients, especially the elevation of IL-6 is remarkable. For this reason, cytokine suppression treatments have come into question in the treatment of these patients. Tocilizumab is an agent that functions as an IL-6 monoclonal antagonist. Tocilizumab has recently come to the fore as a medicine that has shown serious benefits in clinical improvement in severe COVID-19 pneumonia. Some studies have shown that administration of tocilizumab (4 mg/kg/d) given through intravenous infusion at 24-hour intervals at the beginning of the patient's SARS is effective in reducing the need for ventilator support and improving lung functions in patients with severe COVID-19 [48].

Corticosteroids have been shown to shorten the intensive care period in COVID-19 patients with severe persistent shock. In one study, it has been shown that 10-day oral or intravenous 6 mg dexamethasone treatment reduces 28-day mortality in patients who need oxygen or require ventilator support [49]. It has been reported to be beneficial only to patients with COVID-19 with respiratory failure [50]. Its effect has not been demonstrated in patients who do not need respiratory support.

Studies on convalescent plasma therapy continue, and the studies so far have shown that it is useful in the treatment of severe and life-threatening COVID-19 infection. It has been reported to be more beneficial especially when administered before intubation [51].

In addition to all these treatments, the medicines used by the elderly infected with COVID-19 should be evaluated and necessary recommendations should be made due to their comorbidities. For example; Angiotensin-converting enzyme 2 (ACE2) is a co-receptor for viral entry into SARS-CoV-2; this suggests that it has a role in the pathogenesis of COVID-19. Therefore, angiotensin-converting enzyme inhibitors (ACEIs) and Angiotensin II receptor blockers (ARBs) use are thought to increase COVID-19 mortality and morbidity. However, some studies have shown that ACEIs prescribed at the clinic do not inhibit ACE2, which acts as a carboxypeptidase [52]. As a result, no evidence was found regarding the benefit or harm of ACEI/ARB use in observational studies. Elderly patients who are currently using ACEI/ARB as antihypertensive do not need to discontinue the medicine unless they have a different indication. Although studies are reporting that the use of statins is more likely to increase liver enzymes in patients with COVID-19 infection, there are also studies suggesting that COVID-19 infection increases the risk of acute cardiac damage and therefore the use of statins should be continued. Therefore, evaluation of the use of statin on an individual basis was decided. The ESC guidelines recommended that statins be continued in patients who use them because of their immunomodulatory and cardioprotective effects [53]. Also, when using antipyretic in elderly patients; considering the renal failure, toxicity, and gastrointestinal bleeding side effects, nonsteroidal anti-inflammatory medicines (NSAIDs) should be avoided as much as possible, and paracetamol should be preferred primarily.

During the pandemic period, elderly patients without COVID-19 infection who remain at home and immobile for a long time should be evaluated in terms of sarcopenia and malnutrition, which are important geriatric syndromes, and necessary supportive treatments and recommendations should be made. Also, malnutrition and sarcopenia may increase the frailty of patients, causing them to have a more serious COVID-19 infection.

Another important point that should not be ignored during the pandemic process is that the elderly are undoubtedly affected psychologically. The curfew imposed on people aged 65 and over in many countries and their relatives' not visiting them to protect the elderly from COVID-19 infection caused social isolation and some psychological problems. Psychological problems may also cause more malnutrition and frailty in the elderly, leading to a decrease in immune responses and a more serious COVID-19 infection, and increased morbidity and mortality. For this reason, it is very important to evaluate the elderly psychologically and to provide the necessary support during the pandemic process.

CONCLUSION

It is known that the elderly are the most affected group by the COVID-19 epidemic that affects the whole world. The initial symptoms and course of the disease in the elderly may differ from other age groups. Therefore, these differences should be taken into consideration when evaluating geriatric patients. Although there is no difference in the treatment protocol, the comorbidities of the elderly and multiple medicine use should be considered, and alert should be made in terms of medicine side effects and drug-drug interactions. In addition, it

should not be forgotten that elderly patients are affected by the epidemic not only physically, but also socially and psychologically, and the necessary support should be provided in these areas.

Chapter 461

SARS COV-2 IN PEDIATRIC PATIENTS: HEMATOLOGICAL FACE OF THE DISEASE

Tulin Tiraje Celkan* and Ayşe Gonca Kacar

Istanbul University- Cerrahpasa, Cerrahpasa Medical Faculty,
Department of Pediatric Hematology and Oncology, Istanbul, Turkey

ABSTRACT

The COVID-19 pandemic is the biggest health problem of our last 10 months, Pediatricians were more fortunate than internal medicine specialists due to the low number of pediatric cases with COVID 19. As the disease spread rapidly throughout the world, the experience with the diagnosis, follow-up, and treatment are collected. There is no clear-cut data for an effective drug against the SARS-CoV2 virus or an effective vaccine to prevent infection. On the other hand, epidemiological data from infected people are promising for the strategy for future. Unlike other infectious diseases, the incidence of the infection and mortality rate is significantly higher in developed countries. COVID 19 is generally mild in children, some might not show any symptoms at all. In this paper, we tried to share latest data about childhood COV-2 infection, especially focused on hematological signs and symptoms and their physiopathology.

Keywords: COVID 19 pandemic, pediatric cases, hematological signs

INTRODUCTION

Coronaviruses are a group of RNA viruses with a roughly 30 kb genome surrounded by a protein envelope belonging to the *Coronaviridae* family, *Nidovirales* order [1]. The exact origin of the virus is unknown but current studies have revealed that 2019-nCoV has a zoonotic origin, it emerged from a bat-borne virus. It can easily spread between persons through respiratory droplets [2]. It has resulted in a worldwide outbreak and is classified as a

* Corresponding Author's Email: tirajecelkan@yahoo.com.

pandemic by the World Health Organization on March 11, 2020 [3]. By March 1, 2020, SARS-CoV-2 had led to 80 981 confirmed cases of COVID-19 in China, and 44 067 cases in 117 countries. In Korea, the ratio of patients younger than 19 years is 6.7% of total cases, and no child deaths have been reported [4].

Italy, having the second-highest number of Covid-19 infections and the greatest number of deaths after China, reported that children younger than 18 years of age who had Covid-19 composed only 1% of the total patients; and only 11% of these children were hospitalized, and none died [5]. Recent reports on pediatric cases of COVID-19 suggest that COVID 19 is less common in children and they usually have mild illnesses. However, the full spectrum of illness in children is not clearly understood because many pediatric patients might not have been subject to viral testing. Furthermore, there is limited information regarding the duration of SARS-CoV-2 RNA detection in children's respiratory tracts [4]. Thus far, all pediatric cases with laboratory-confirmed 2019-nCoV infection were mild cases, and no deaths had been reported.

TRANSMISSION

Respiratory droplets and contact are the main transmission routes in COVID 19 [6]. The incubation period is about 1 to 14 days, and that can last up to 24 days. The virulence of the virus could peak 2 to 3 days before symptom starts, and transmission during the presymptomatic stage is estimated to make up %44 of secondary infections [4]. At the beginning of the Sars COV- 2 outbreak, the infection is transmitted by adults in the community. Then the virus spread to the family and children via infected adults. The first pediatric case was identified in the familial cluster [7]. Close contact with symptomatic or asymptomatic cases with silent infection are the main transmission routes of 2019-nCoV infection in children [6]. Children tend to have no or milder symptoms, so they can easily spread infection to their household. Therefore understanding infectious burden and potential for transmissibility within the pediatric population is critical for developing both short- and long-term responses, including public health policies, to the current pandemic [8]. There is an urgent need for further investigation of the role of children who have an important role in the chain of transmission.

Perinatal transmission of COVID 19 is also not known exactly. There are several reported cases of neonatal infection suggesting a possible neonatal and vertical transmission. In a study by Chen et al., nine neonates born to COVID 19 positive mothers tested negative after cesarean delivery [7]. Breastmilk and placental pathological specimens from COVID 19 positive mothers remained negative for the viruses. Like other coronaviruses (SARS and MERS) it is thought that vertical transmission during third trimester is very rare. But the consequences of SARS COV-2 in early pregnancy like abortion, premature delivery, malformations, organ development is not well known. Also, Dong et al. emphasize that the proportion of severe and critical cases were higher in neonates when compared to the other childhood age group [9]. Breastmilk of the mother with suspected or confirmed COVID 19 is still the first choice in newborns feeding. Secretory IGA in breastmilk can be protective against COVID 19. Also, breastmilk improves the neurocognitive and immunologic development of the newborn.

CLINICAL PRESENTATION

Children infected with COVID 19 might be asymptomatic or generally presented with fever, dry cough, fatigue, and have mild upper respiratory symptoms. Gastrointestinal complaints like abdominal discomfort, nausea, vomiting, diarrhea and are rarer clinical symptoms of pediatric COVID 19 [6]. ACE2 the receptor for SARS-COV-2 in human cells is highly expressed in olfactory neuroepithelium lead to the infection in this site, resulting as a typical symptom, anosmia. The severity of COVID-19 was defined based on the clinical features, laboratory testing, and chest X-ray imaging, including asymptomatic infection, mild, moderate, severe, and critical cases. The diagnostic criteria were as follows [10]:

1. **Asymptomatic infection:** Patient has no clinical symptoms and signs and the chest imaging is normal, while the 2019-nCoV nucleic acid test is positive.
2. **Mild:** Patient is presented with acute upper respiratory tracts infection symptoms like fever, fatigue, myalgia, cough, sore throat, coryza. Some cases may have no fever, or have only digestive symptoms such as nausea, vomiting, abdominal pain, and diarrhea.
3. **Moderate:** Pneumonia occurs, frequent fever and cough, mostly dry/productive cough, some may have wheezing, but no obvious hypoxemia such as shortness of breath, and dry snoring, and/or wet snoring. Some cases may have no clinical signs and symptoms, but chest CT shows subclinical lung lesions.
4. **Severe:** The disease usually progresses and dyspnea occurs, with central cyanosis. Oxygen saturation is less than 92%, with other hypoxia manifestations.
5. **Critical:** Children can quickly progress to acute respiratory distress syndrome (ARDS) or respiratory failure, and may also have shock, encephalopathy, myocardial injury or heart failure, coagulation dysfunction, and acute kidney injury.

In Dong's study, 94.1% of all patients were confirmed as asymptomatic, mild, or moderate cases, 5.9% of them were severe. Severe cases and their proportion was 10.6%, 7.3%, 4.2%, 4.1%, and 3.0% for the age group of <1, 1-5, 6-10, 11-15, and ≥ 16 years, respectively [10]. This study revealed that children under 5 years old, especially infants with COVID-19 had more severe disease than the others.

A study suggests that children are just as likely as adults to become infected with SARS-CoV-2 but are less likely to be symptomatic or develop severe symptoms [11]. In several studies, it is reported that children and younger adults who do not have underlying conditions, such as impaired lung function or immunosuppression, have a much lower risk for severe forms of COVID-19 [12].

There are some suggested hypotheses for this viewpoint:

1. The immune system of children and adults is different from composition and responsiveness. Also immune system's function and component developed with the age of the children (infant, preschool, adolescent)
2. Presence of other simultaneous viruses in the mucosa of lungs and airways, which are common in young children, could limit the growth of SARS-CoV2 by direct

virus-to-virus interactions and competition [8]. As the amount of viral copy is diminished; the severity of COVID 19 is reduced.

3. The angiotensin-converting enzyme (ACE) 2 receptor is necessary for SARS-Cov2 binding and infection. These receptors in children are relatively less than adults. ACE2 expression did not correlate with viral load, suggesting that although increased ACE2 expression increased susceptibility for infection, once infected, children could carry high viral loads regardless of level of ACE2 expression.
4. In severe COVID-19 infection; the viral and pulmonary phases are followed by the final hyperinflammatory phase, which can lead to severe acute respiratory distress syndrome (ARDS), impaired cardiac function, and death. Children are less inclined to develop ARDS during respiratory tract infections than adults.

Although children tend to have mild clinical forms of COVID 19 or they are asymptomatic, they can have a large number of viruses and transmit to the other people easily. Also, viruses can persist in feces long after they are absent from nasopharyngeal secretions. For coping with this pandemic, we must protect the children from COVID 19 infection [12].

While acute SARS-CoV-2 infection tends to be mild or symptom-free in most pediatric cases, some children develop a multisystem inflammatory syndrome (MIS-C). Several weeks after possible SARS-CoV-2 infection or exposure, with severe cardiac complications, including hypotension, shock, and acute heart failure. MIS-C criteria, defined by Centers for Disease Control and Prevention (CDC): fever $>38^{\circ}\text{C}$ for >24 hours, laboratory evidence of inflammation, at least two organs involved, and no alternative possible diagnoses and a positive SARS-CoV-2 test by RT-PCR, serology or antigen test, or exposure to a COVID-19 positive patient within 3-4 weeks before the onset of symptoms. In Yonker's et al. study although 11-16 years of group children were mostly affected by COVID 19, the children ages 1-4 years and males are the most highly presented with MIS-C. In addition to fever, MIS-C complained more often about nausea/vomiting and rash and few symptoms of an upper respiratory tract infection. Co-morbidities like asthma, heart disease, hypertension, and diabetes do not differ between MIS-C positive/negative COVID 19 children. Children with severe MIS-C (with hypotension or cardiac abnormalities requiring therapeutic intervention such as steroids, IVIG, and/or anakinra) have more elevated IgM and IgG. Children with MIS-C do not have high levels of viral load on nasopharyngeal or oropharyngeal viral testing, nor do they have detectable viremia, however, they do have hyperactive antibody responses. Children with severe MIS-C have elevated SARS-CoV-2 IgM and IgG levels, showing T and B cell over-reactivity, or auto-antibodies that may be driving an inflammatory process causing MIS-C [8].

IMAGING

Like other types of pediatric pneumonia, chest plain film (CXR) is not indicated for most pediatric patients with known or suspected COVID-19 with mild clinical symptoms that do not require hospitalization; although CXR is usually indicated in neonates with fever and respiratory symptoms[13]. Sequential CXRs may be helpful to assess pediatric patients with

COVID-19 who demonstrate worsening clinical symptoms or to assess response to supportive therapy. However, routine daily chest radiographs for stable pediatric COVID-19 patients in the intensive care unit (ICU) are not recommended as they have not been shown to impact adverse outcomes, pediatric ICU or hospital length of stay, or duration of ventilator requirements.

Chest CT imaging is not recommended as a first imaging modality because of the increased radiation sensitivity of pediatric patients. In some clinic situation, for example, the pediatric patients presenting with acute symptoms (i.e., hypoxia, dyspnea, tachycardia), worrisome abnormal laboratory findings (such as an elevated D-dimer), or to evaluate a patient demonstrating clinical deterioration or not responding as expected to supportive treatment, chest CT can be the appropriate diagnostic method [13].

Although CXR is the first imaging study recommended for evaluation of pediatric COVID-19 disease, most of the SARS- COV2 pediatric patients were not severe, plain chest X-ray could not identify all the pulmonary lesions, so Chest CTs were obtained to provide supportive information for diagnosis and management. CXR sensitivity for detection of COVID-19 pneumonia in adult patients has been reported ranging from 69% to 89%. A single pediatric COVID-19 study reported observing patchy unilateral opacities in 40% of patients. In some suspected pediatric patients with a negative nucleic acid of COVID-19 virus, chest CT findings revealed the diagnosis, which could provide the early treatment of the children and also isolation of the source of infection [14].

CT images of pediatric COVID 19 are similar to those in adults. The typical radiologic findings are unilateral or bilateral subpleural ground-glass opacities, and consolidations with surrounding halo sign. Pleural effusion was not seen. The absorption of lesions on chest CT lagged behind clinical symptoms and nucleic acid detection. Lesions could be still visible on chest CT when two consecutive nucleic acid tests were negative.

Bacterial coinfection and other viral infections are more common in pediatric COVID, so the CT imaging of COVID-19 infection should be differentiated with other virus pneumonia. Adenovirus pneumonia lesions had a higher density, more consolidations, and fewer subpleural lesions. Respiratory syncytial virus and parainfluenza virus pneumonia lesions were mostly distributed along the bronchial tree with a thickened bronchial wall. Influenza viruses could cause grid-like changes in the lungs. In addition, it should be differentiated from bacterial pneumonia, mycoplasma pneumonia, and chlamydia pneumonia, and the density of pneumonia lesions caused by the latter pathogens is relatively higher. COVID-19 pneumonia can be superimposed with pneumonia caused by other types of pathogens, presenting more serious and complex imaging manifestations, so epidemiological and etiological examination should be combined.

Imaging findings in post-COVID 19 Multisystem Inflammatory Syndrome in Children (MIS-C), including airway inflammation, rapidly progressive pulmonary edema, coronary artery aneurysms, and extensive abdominal inflammatory change within the right iliac fossa, with lymphadenopathy and bowel wall thickening. In Hameed et al. study, central bronchial wall thickening is commonly seen in these children (34%) and with none exhibiting lower respiratory tract symptoms. These findings are more likely attributable to airway inflammation and pulmonary arteritis. Echocardiography must be done in MIS-C because it has more aggressive cardiovascular findings than that in Kawasaki disease. Abdominal USG/CT showed features of right iliac fossa mesenteric inflammation and lymphadenopathy.

The clinical findings of MIS-C overlap with Kawasaki disease and ischemic stroke as a complication of vasculitis seen in both diseases [15].

Furthermore, as no long-term data is yet available, future studies investigating post-recovery sequelae of disease including alterations of pulmonary function tests and risk for development of permanent lung injury such as pulmonary fibrosis will be important [13].

LABORATORY FINDINGS

In SARS-COV2, some of the inflammatory biomarkers are associated with poor prognosis. C-reactive protein (CRP) elevation was seen in up to 40% of patients and associated with ARDS, cardiac injury, and mortality. Elevated LDH and serum ferritin levels have also been linked in multiple retrospective analyses with a higher risk of ARDS and death. Interleukin-6 (IL-6) was elevated at admission in 52% of patients in a study by Chen et al. and linked to increased mortality [16, 17]. Blood counts and coagulation parameters are deteriorated in severe COVID 19. Lymphopenia, thrombocytopenia, and coagulopathy indicate severe illness and often progress to the disseminated intravascular coagulation (DIC). COVID-19 has also been associated with an increased risk of venous thromboembolic events (VTE).

Lymphopenia

In a retrospective analysis of patients in Hong Kong and Singapore, lymphopenia was first described with SARS-CoV in 2003. It has been associated with adverse outcomes and intensive care unit (ICU) stay. Severe lymphopenia ($< 0.6 \times 10^9/L$) can be considered as one of the indicators of early admission to ICU. Li and Wang et al. reported that there was no correlation between WBC count and severity of the disease. It was also shown that lymphopenia can develop when the leukocyte count was normal [18]. Patients with severe infection were observed to have a significantly lower lymphocyte count and the lymphocyte/WBC ratio. Guan et al. obtained clinical data and showed that on admission, 83.2% of patients had lymphopenia and 33.7% had leukopenia. Thrombocytopenia was also seen in 36.2% of cases, as discussed later. On the other hand, anemia was usually not present with hemoglobin values at normal to very mildly decreased. Hematologic abnormalities were more prominent in patients with severe disease when compared to non-severe presentations. [16]. Wu et al described similar findings with 64% of patients having lymphopenia at presentation. Decreased lymphocyte counts were associated with poor prognosis and an increased risk of ARDS [19]. Lymphopenia was again documented in 70.3% of patients in Wuhan, with lymphocyte count, $>1100/mL$ were significantly less likely to have a severe illness than those in the 0–500/ mL and 500–1100/mL ranges [20]. Tan et al. emphasized that blood lymphocyte percentage (LYM%) showed the most significant and reliable trend in predicting disease progression [21]. Days 10–12 and 17–19, patients whose lymphocyte percentage was less than 20% and 5%, had the worst clinical outcomes.

The pathophysiology of the association between lymphopenia and clinical course and prognosis is multifactorial. In the incubation period, lymphocyte count is in the normal range.

As the virus spreads and concentrates in tissues (lungs, heart, gastrointestinal tract via cell receptor for the SARS COV2 (the angiotensin-converting enzyme 2 (ACE2)), symptoms worsen and radiographic findings become more evident. At this point, both T- and B- cell lymphocyte counts decrease in conjunction with a significant rise in inflammatory markers [22]. Excessive increase in cytokines causes exaggerated inflammatory response named as a cytokine storm. That is characterized by increases in levels of IL-2, IL-6, IL-7, tumor necrosis factor (TNF)- alpha and granulocyte colony-stimulating factor, promoting lymphocyte apoptosis. The ACE receptor is also expressed on the surface of a lymphocyte that was infiltrating various organs of the oral mucosa and the lungs etc. Thus, this can be the other mechanism of the observed lymphopenia, involving direct cytotoxic effects of the virus and cell membrane lysis. Inhibitory effects of lactic acidemia on lymphocytes can be the other potential contributing factors to the development of lymphopenia [23].

Thrombocytopenia

Thrombocytopenia is one of the pathologic laboratory findings that can be seen in SARS COV2 positive patients. Contrary to these findings, some authors reported that patients with significantly higher platelets during treatment have longer average hospitalization periods, and patients with higher platelet lymphocyte ratio (PLR) during treatment prolong their average hospital stay [24]. We thought that thrombocytosis, being an acute phase reactant, might be a good marker for infection at the beginning of COVID 19 infection. It has been interpreted that the PLR of the patients could provide a new indicator in the follow-up of patients with COVID-19 and could indicate the degree of the cytokine storm. Liu et al. also looked into the association between platelet parameters and mortality from COVID-19: In a series of 383 patients, thrombocytopenia at admission was linked to a three-fold increase in mortality compared to patients with normal platelet counts. An increase of $50 \times 10^9/L$ of platelets was found to be associated with a 40% decrease in mortality [25]. During the infection period thrombocytopenia is not generally severe enough to cause bleeding complications.

Thrombocytopenia is likely multifactorial and several contributory mechanisms have been postulated. Viral epitopes circulating in the bloodstream would mimic antigens present on platelet surfaces and lead to the formation of antibodies and the platelet- antibody complexes would be destroyed through a complement independent immune-mediated response, just like ITP [26]. Furthermore; multiorgan failure, disseminated intravascular coagulation (DIC) is a common risk for thrombocytopenia. Endothelial damage triggered by a systemic inflammatory response and mechanical ventilation leads to hyperactivation of platelets and thrombosis causing disseminated platelet consumption.

Eosinopenia

Eosinophils are the type of white blood cells that are usually linked with allergic and parasitic diseases. Now they have been demonstrated to possess antiviral capacities and enhance the immune response and reduce the inflammation. It is currently not known whether

COVID-19 patients with eosinopenia are also more likely to develop into critical illness. In Zhang's study, 35.3 % of patients showed a decrease in eosinophil absolute number ($<0.02 \times 10^9$). Compared with normal eosinophil groups, eosinopenic patients showed serious vital signs on admission, with faster heart rate and relatively higher temperature and a greater proportion of eosinopenic patients were fell into severe conditions. Eosinopenic patients tended to have a lower lymphocyte count and monocyte absolute number. Following the inflammatory markers, eosinopenic patients have higher high sensitive C-reactive protein and procalcitonin. These findings revealed that eosinophils play an important role in maintaining immune regulatory system, by producing inflammatory and homeostatic mediators. Eosinophils were responsible for local immunity and tissue repair. The pathophysiology for eosinopenia in COVID-19 could be multifactorial, involving the suppressed eosinophil egress from the bone marrow, inhibition of eosinophilopoiesis, reduced eosinophil-driving cytokines, or direct interferon-induced apoptosis. IL -33 is responsible for eosinophil activation in the airways, bone marrow, and ciliated epithelial cells which are the main target of coronavirus. Also, IL -33 activates the innate lymphoid cells that produce IL-5 which is important for eosinophil cumulation in the airways. Eosinopenia was very frequent in COVID-19 and could be used in the early prediction of severity before clinical symptoms have significantly worsened, which may help clinicians in identifying potentially severe cases with COVID-19 [2].

COAGULATION DISORDERS IN COVID-19

SARS-CoV-2 infection is often associated with hypercoagulability and disseminated intravascular coagulation (DIC). This hypercoagulability is manifested as progressive lung and kidney disease, pulmonary emboli (PE), venous thrombotic events (VTE), recurrent line obstruction, and stroke in adults (SARS-CoV-2) infection.

It is thought that SARS-CoV-2 virus was diffusely present in endothelial cells and the virus uses the ACE2 receptor to directly infect the endothelium and recruit immune cells. Inflammation of the endothelium leads to microvascular dysfunction, vasoconstriction, organ ischemia, and a hypercoagulable state [27].

Although many authors recommend anticoagulation of hospitalized symptomatic adults with COVID-19, guidelines regarding the thrombotic evaluation and anticoagulation management of hospitalized children with COVID-19 remain lacking. Pediatric hematologists developed pediatric recommendations for children hospitalized due to SARS-CoV-2 infection after revision of anticoagulation recommendations for adults [28]. Fibrinogen and D-dimer are elevated and correlated with acute inflammatory markers such as C-reactive protein. Prothrombin time prolongation is often seen. Unlike classic DIC laboratory findings, a platelet count that is only mildly decreased, a partial thromboplastin time that is normal-to-mildly prolonged, and no signs of microangiopathy and bleeding in contrast to DIC. While an elevated D-dimer may also reflect underlying inflammation, immobility, or liver disease, patients with COVID-19 infection with markedly raised D-dimers are significantly at risk of mortality, and a raised level also implies increased thrombin generation [29].

In the coagulation cascade, activated factor V interacts with activated factor X to form the prothrombinase complex, which catalyzes formation of thrombin and leads to fibrin clot

formation. Dysregulation of factor V due to factor V Leiden is a well-known cause of a prothrombotic state. Concurrent elevations of factor V activity and factor VIII activity have also been linked to increased VTE risk. In Stefely's study factor V was significantly elevated in the COVID-19 cases (median 150 IU/dL) compared to both control cases on ventilators and the non-ventilated ones. These findings suggest that the elevation of factor V in severe COVID-19 cannot be simply explained by a general state of severe illness or by ventilator use. Together with the rarity of factor V elevations before the COVID-19 pandemic, these findings suggest a more specific relationship between COVID-19 and factor V elevation. High factor V levels in COVID 19 can be explained by the high amount of megakaryocytes in patient's organs which contain %20-25 of the factor V. While patients with severe COVID-19 might initially present with markedly elevated factor V activity, a subsequent decline in factor V activity could be associated with clinical decompensation. For these reasons factor V can be a candidate biomarker for future clinical trials investigating VTE and anticoagulation therapies in patients with COVID-19 [30].

As there are no clear-cut definitions for anticoagulation for pediatric hospitalized VTE patients, prophylactic anticoagulation may be considered for children with the following risk factors: (a) strong personal or family history of VTE, or (b) an indwelling central venous line and two or more additional risk factors, or (c) four or more risk factors. Prophylactic anticoagulation therapy in children must be done by considering bleeding risk. Confirmation of VTE by imaging may not be needed prior to treatment with anticoagulation if clinical suspicion is high. Therapeutic anticoagulation is considered for the children who used anticoagulation prior to admission and those who are receiving extracorporeal organ support. Catheter-directed alteplase and mechanical thrombolysis can be used for hemodynamically unstable PE or limb-threatening deep vein thrombosis. Use of systemic alteplase for progressive respiratory failure is still investigating. As the pediatric experience in COVID-19 increases, new recommendations for laboratory and imaging evaluation, assessment of thrombotic risk, and anticoagulation therapy in the pediatric patient will be improved [28].

TREATMENT

Although (COVID-19) is mild in nearly all children, a small proportion of pediatric patients develop a severe or critical illness. The four main principles for adequate therapeutic management are early identification, isolation, diagnosis, and treatment [31]. If there is a suspicion about COVID 19 the patient must be isolated in a single room to prevent the possible transmission of disease before laboratory confirmation. Mild cases should be isolated and treated with symptomatic relief medication, preferably paracetamol or dipyrone, to control fever.

The majority of children with COVID-19 experience a mild, self-limited illness, and there is a lack of evidence of efficacy for any antiviral, and due to the possible harms of these medications, the risk-to-benefit ratio must be considered for pediatric patients. Our experience in a hematology-oncology ward also supports the therapy which is tailored for each patient for beginning anticoagulation, antiviral regimens besides supportive therapy. Therefore supportive care is the mainstay of the management strategy [32].

The clinical presentation of COVID-19 in children overlaps significantly with other infections. No clinical, radiographic, or laboratory criteria are sufficiently specific to distinguish COVID-19 from these other pediatric conditions. So that antiviral drug therapy must be started after confirmation of SARS COV 2 infection. A rare exception might be made for critically ill patients with a high suspicion for COVID-19 [32].

Children with mild or moderate disease (there is no need for O₂ therapy) recover with supportive care alone. Administration of antivirals early in the disease course to prevent progression thus does not seem warranted because of the possible harms of these drugs. Most children with severe infection will recover with supportive care alone. Use of potentially active antivirals could be considered on a case-by-case basis, taking into account underlying medical conditions and health status that may confer risk for progression to more serious illness.

Antiviral Treatment

Supportive care is the suggested approach for nearly all children. Antivirals may be considered on a case-by-case basis according to underlying conditions. (Table 1)

If an antiviral is used, the panel suggests remdesivir as the preferred agent. Remdesivir is a nucleoside analog prodrug that, when activated, binds to viral RNA-dependent RNA polymerase, resulting in premature RNA chain termination. A recent case series of 53 patients with severe COVID-19 pneumonia who received remdesivir under a compassionate-use protocol reported clinical improvement in 68% after a median follow-up of 18 days, with 13% mortality and a generally acceptable toxicity profile [33]. Efficacy in pediatric patients and optimal dosing, duration of therapy is not established yet.

The Infectious Disease Society of America (IDSA) guideline panel for COVID-19 treatment, recommends hydroxychloroquine/chloroquine in the context of a clinical trial [33]. The antiviral activity is inhibition of viral entry into human cells by increasing the pH of the endosomes required for cell entry, broad anti-inflammatory and immunomodulatory effects, and inhibition of glycosylation of the ACE-2 receptor, the binding site for SARS-CoV-2 [34]. The recommended dose is 3–5 mg/kg/day (max dose 400 mg) hydroxychloroquine sulfate iv, in pediatric patients, twice daily for five days. The use of azithromycin in combination with hydroxychloroquine was associated with a more rapid resolution of virus detection than hydroxychloroquine alone [35]. But combined use of these drugs potentiate QTc prolongation.

According to Chen's review in pediatric patients, interferon- α 2b nebulization (100,000–200,000 IU/kg for mild cases, and 200,000–400,000 IU/kg for severe cases, two times/day for 5–7 days.) can be applied [36].

Favipiravir is an RNA polymerase inhibitor. It is thought to have potential antiviral action on SARS-CoV-2. In February, a clinical trial on favipiravir for the treatment of COVID-19 was initiated, and results were promising. The preliminary results from a total of 80 patients indicated that favipiravir had more potent antiviral action than lopinavir/ritonavir which were protease inhibitors approved by the FDA for treatment of pediatric HIV [33].

Immunomodulator Treatment

Pediatric COVID-19 patients with hyper inflammation whose illness progress to critical COVID-19 may be considered for immunomodulatory treatment. Small subset of pediatric patients is severely affected by COVID-19 with a presentation ARDS, hypercoagulability, hyper inflammation, and multiorgan failure [37]. There are no immunomodulators with proven efficacy for the treatment of COVID-19 in pediatric patients as of July 24, 2020. Therefore, no guidance can be provided to support the use of one immunomodulatory therapy over another. If immunomodulators are used in the treatment of COVID-19, patients should be monitored for adverse effects [38].

IL-6 and IL-1 inhibition may be considered in the care of pediatric patients with critical COVID-19 with priority given to clinical trial enrollment if available. Anakinra can be used as an IL-1 inhibitor based on its safety profile and favorable pharmacokinetics. Glucocorticoid therapy may be considered for pediatric patients with critical COVID-19 with a preference for use in the setting of clinical trials, if available. Steroid is indicated like asthma or catecholamine-refractory shock in COVID 19 pediatric patients.

Convalescent plasma in pediatric COVID-19 may be considered as part of the recently established FDA emergency investigational new drug program if in the United States or as part of a clinical trial. The efficacy of passive transfer of convalescent plasma (CP) is thought to be mediated primarily through viral neutralization, although other mechanisms such as stimulation of antibody-dependent cellular cytotoxicity and enhanced phagocytosis have also been postulated. While the passive transfer of polyclonal antibodies via convalescent plasma may be of benefit, no SARS-CoV-2-specific monoclonal antibody therapies have yet been clinically tested. It is recommended that children >40 kg be dosed with 200–500 mL and children <40 kg be dosed with 10–15 mL/kg, while being aware of volume overload, especially in children with cardiac dysfunction.

The use of IVIG for treatment of acute COVID-19 in pediatric patients is not recommended except for (ya da sadece except) specific clinical situations in which IVIG is typically used and treatment of MIS-C.

JAK inhibitors and Type I or type III IFN should not be used for pediatric COVID-19 patients outside of a clinical trial.

Severe cases with respiratory distress and/or hypoxia ($\text{SaO}_2 < 94\%$) should be admitted to the hospital. Indications for ICU admission are respiratory failure requiring mechanical ventilation, shock, or other organ dysfunction requiring treatment. The main treatment principles of ARDS are as follows [39] :

1. Early tracheal intubation – rapid sequence intubation is the best practice in this situation. Preoxygenation should be performed using a flexible nasal cannula (up to flows of 4 L/min) or a reservoir mask with a lower flux to maintain a $\text{SaO}_2 > 93\%$. Positive pressure ventilation with a bag-valve-mask or other similar apparatus should be avoided not to generate aerosols.
2. Non-invasive ventilation (NIV) should be avoided because of the high risk of aerosol dispersion and contamination among health practitioners.
3. The patient should be maintained in a prone position at least 18 hours per day

4. Protective mechanical ventilation and closed tracheal aspiration systems should be used.
5. Antibiotics should be used only in patients with secondary bacterial infections based on the culture and antibiogram results. Corticosteroids can suppress lung inflammation but also inhibit immune responses and pathogen clearance, and should be avoided except for those with a specific indication (e.g., bronchospasm or some cases of septic shock) Intravenous immunoglobulin can be used in critically ill child [40].
6. Fluid therapy or vasoactive/inotropic drugs and renal replacement therapy may be needed.
7. Anticoagulation is required in presence of high D-dimers or evidence of thromboembolism [33].

VACCINATION TRIAL

NVX-CoV2373 contains Matrix-M1 adjuvant and a recombinant SARS-CoV-2 (rSARS-CoV-2) nanoparticle vaccine, constructed from the full-length (i.e., including the transmembrane domain), wild-type SARS-CoV-2 spike glycoprotein, which mediates attachment of the virus to the human angiotensin-converting enzyme 2 (hACE2) receptor of host cells for cellular entry and serves as a key target for the development of antibodies and vaccines. The spike protein of vaccine induces high titers of antibodies that blocked hACE2 receptor binding and achieved neutralization of wild-type virus. The magnitude of response is higher than that is measured in human convalescent serum. Polyfunctional CD4+ and CD8+ T-cell responses were induced with a T helper 1 (Th1) dominant phenotype. Keech et al. initiated a randomized, placebo-controlled, phase 1–2 trial to evaluate the safety and immunogenicity of the rSARS-CoV-2 vaccine in 131 healthy adults [41]. In phase 1, vaccination comprised two intramuscular injections, 21 days apart. At 35 days, NVX-CoV2373 appeared to be safe, and it elicited immune responses that exceeded levels in Covid-19 convalescent serum. The Matrix-M1 adjuvant-induced CD4+ T-cell responses that were biased toward a Th1 phenotype. Phase 2 has commenced based on the safety results of the day 35 primary analysis, and phase 3 is in preparatory stages.

Mycobacteria is previously reported to be potent Th1 stimulants [42]. Such an antigen stimulation may increase proliferation in favor of Th1 cells, Bacillus Calmette-Guerin (BCG), a live attenuated vaccine, is being administered routinely against Mycobacterium. BCG can induce sustained nonspecific reactions to infections at the level of trained immunity and heterologous Th1/Th17 responses by prolonged production of IFN- γ , IL-17, and IL-22. In Ozdemir et al. study, the mean of cases per population ratio is statistically significantly lower in BCG-vaccinated countries than in BCG-non-vaccinated countries [42]. The mean of deaths per case ratio is also significantly lower in BCG-vaccinated countries. In the Northern Hemisphere, the mean of deaths per population ratio is also found to be significantly lower in BCG-vaccinated countries than in BCG-non-vaccinated countries. Therefore it is thought that BCG vaccination has a protective role against COVID 19 infection by its immunomodulator effect. There are also many kinds of vaccines trial (inactive, recombinant) whose phase 3 trials are ongoing.

CONCLUSION

Recent studies about pediatric COVID 19 revealed that this disease is less common and mild in children. Full-spectrum of illness in children is not clearly understood because many patients might have not been subject to viral testing. At the beginning of SARS COV-2 outbreak, the children are isolated so the virus are transmitted by adults in the community. Therefore, at the beginning of the pandemic, disease was mostly seen in adults. Although ACE receptor that increased susceptibility for infection is relatively less than adults, once the children are infected, they could carry high viral loads. As the pandemic progressed, more children infected, transmission rate of virus is increased.

For coping with this outbreak, we must protect the children from SARS COV-2 by social distancing and using facial masks. The decision to open up schools and daycare centers should be reconsidered until the severity of the pandemic subsides.

ABSTRACT

The emergence of coronavirus disease 2019 (COVID-19) pandemic due to severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) led to a global health crisis. After the report of the first case in Wuhan, China, in December 2019, millions of people were infected with the virus in only a few months. Apart from many systemic findings such as fever, fatigue, dry cough, the disease can also involve the eyes mainly in form of conjunctivitis. Therefore, all patients with red eyes became suspicious of COVID-19 conjunctivitis. Ophthalmologists are at increased risks for COVID-19 because of their close physical proximity to the patients during the eye examination. Thus, eye care providers should use proper ways of protection including wearing an N95 mask, gloves, and protective goggles. The outpatient clinics should be disinfected regularly and social distancing should be provided for all areas. Regular visits without any emergency should be postponed or those patients should be managed via telemedicine. Urgent or visually important cases should be triaged for COVID-19 risk before the ophthalmological examination. International guidelines should be followed for determining the effective and safe treatment protocols for the patients during the pandemic.

Keywords: ophthalmology, COVID-19, social distancing, severe acute respiratory syndrome

INTRODUCTION

The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is a highly contagious RNA virus, causes Coronavirus disease 2019 (COVID-19) emerged on the last days of December 2019 in Wuhan city, Hubei province, China. COVID-19 is the third and largest coronavirus outbreak in the 21st century after the severe acute respiratory syndrome (SARS) in 2002 and the Middle East respiratory syndrome (MERS) in 2012. Over 80 million people have been infected and the COVID-19 has caused more than one million deaths.

There are seven types of coronaviruses known to infect humans: 229E (alphacoronavirus), NL63 (alphacoronavirus), OC43 (betacoronavirus), HKU1 (betacoronavirus), MERS-CoV (betacoronavirus), SARS-CoV (betacoronavirus), and the most recent SARS-CoV-2 [1]. Although not proven, the source of the disease has been speculated to be from bats [2].

COVID-19 can potentially be fatal and affects mainly the lungs and airways leading to the most frequent symptoms of the disease including fever (87.9%), dry cough (67.7%), and fatigue (38.1%) [3]. However, apart from the respiratory tract, it can also affect other regions including the gastrointestinal tract and ocular tissues [4, 5]. So, the manifestations of COVID-19 in other organ systems should not be ignored as they can represent an alternative mode of transmission.

From genomic and structural analyses, it has been reported that the SARS-CoV-2 has a similar receptor-binding motif as SARS-CoV, which allows it to infect host cells via the angiotensin-converting-enzyme-2 (ACE2) [6]. ACE2 has been found in the aqueous humor [7], conjunctiva, and corneal epithelium [8].

Conjunctival congestion or conjunctivitis can be an early clinical manifestation of COVID-19. In a study with a large case series, 0.8% prevalence was seen in China [9]. Previous studies reported that SARS-CoV-2 was found in tear samples of patients with COVID-19 [10]. Apart from conjunctivitis, hyperreflective lesions were observed on the papillomacular bundle and between the retinal ganglion cell layer and inner plexiform layer without causing any visual disturbance in optical coherence tomography [11]. Ophthalmoplegia cases related to COVID-19 have also been reported [12, 13].

Ophthalmologists are at increased risks for COVID-19 because of their close physical proximity to the patients during eye examination (less than 30 cm during the slit-lamp examination, and less than 5 cm at direct ophthalmoscopy examination). Also, manipulation of eyelids in some patients required during the slit lamp examination, which increases the risk of contact with tears or other ocular discharge. Ophthalmologists should routinely wear respiratory masks and gloves if contact is required.

Dr. Li Wenliang, who alerted Chinese government officials of an incipient viral syndrome (COVID-19), was a young ophthalmologist. By his account, he believed he contracted the infection from a glaucoma patient he was evaluating for conjunctivitis; a month after exposure, he passed away due to respiratory failure. With the outbreak of COVID-19, ophthalmologists may be the first to identify patients with COVID-19 seeking treatment for acute conjunctivitis before the manifestation of respiratory symptoms. They have an important role in guiding infection control measures to prevent unnecessary exposures to other patients and medical staff.

Old age is a known risk factor for more severe clinical manifestation of COVID-19 with probable additional systemic diseases (e.g., diabetes mellitus, hypertension, etc.). Cataract, glaucoma, and macular degeneration, common ophthalmic conditions, are associated with aging. Thus, additional increased risk portended to ophthalmic practice relates to the increased age of patients in ophthalmology clinics or undergoing ophthalmic procedures.

The above-mentioned factors make the role of ophthalmologists during the pandemic very crucial.

SARS-CoV-2 IN TEARS AND OCULAR FINDINGS OF COVID-19

From the experience on SARS-CoV, it was known that coronaviruses can be found in tears [4]. However, at the beginning of the pandemic, the ocular involvement of the COVID-19 was unknown. After the report of transmission of the disease in a patient (Guangfa Wang, a member of the national expert panel) who did not wear protective goggles but wore an N95 mask, the possibility of disease transmission via the eyes started to be questioned. Then a report showed that COVID-19 can be transmitted through the mucous membranes including the conjunctiva [14]. Ophthalmologists have also been shown to be infected in several case reports.

Polymerase chain reaction (PCR) analysis of the tear films of the patients with COVID-19 with or without conjunctivitis showed that the virus can be isolated from the patients with COVID-19. The patients with positive PCR in the tear film can be in the early stage of the disease without any systemic symptoms. Therefore, protection of the eyes with goggles is very important to prevent the disease spread during the examination of the patients, and tears of the COVID-19 patients are also potential sources of disease transmission. PCR positivity of the tear of a patient with COVID-19 despite no systemic symptoms 3 weeks after the disease onset should be another warning for the clinicians to be careful with handling ocular tissues or secretions even after the disappearance of the symptoms and negative nasopharyngeal swab [15].

The studies on tear samples of patients with COVID-19 are summarized in Table 1. Ocular findings of the disease were as high as 31.6% and the PCR positivity of the tear samples was as high as 24%. However, a recent meta-analysis showed that the overall prevalence of the ocular involvement in patients with COVID-19 was 5% and 28% of ocular samples showed SARS-CoV-2 PCR positivity [16]. A study on pediatric patients with SARS-CoV-2 positivity showed that asymptomatic COVID-19 pediatric patients could also have positive tear samples [17].

Several possible reasons for tear sample positivity for SARS-CoV-2 have been speculated including direct inoculation of the virus, its migration from the respiratory tract through the nasolacrimal duct, or shedding of the virus from an infected lacrimal gland [25]. The last possible transmission way might be the affinity of SARS-CoV-2 to angiotensin-converting-enzyme-2 in the ocular tissues [8].

Table 1. List of the studies investigating the PCR positivity in tear samples of patients with COVID-19

Study	Sample size	Patients	Ocular findings	SARS-CoV-2 in Tear Samples
Wu et al., [18]	38	Clinical confirmation	31.6%	5%
Xia et al., [19]	30	Laboratory confirmation	3.3%	3%
Seah et al., [20]	17	Laboratory confirmation	5%	0%
Sun et al., [21]	72	Laboratory confirmation	2.7%	1.3%
Deng et al., [22]	114	Clinical confirmation	0%	0%
Zhou et al., [23]	67	Confirmed/suspects	1.4%	4.4%
Karimi et al., [10]	43	Clinical confirmation	2.3%	7%
Arora et al., [24]	78	Laboratory confirmation	0%	24%

SARS-CoV-2: Severe acute respiratory syndrome coronavirus-2.

COVID-19 can lead to some ocular findings including mostly conjunctivitis with complaints of itching and red-eye. Conjunctival congestion was reported in 0.8% (9/1099) of the patients with laboratory-confirmed disease in China [9]. A recent meta-analysis on ocular findings of COVID-19 showed that ocular findings of the disease can be the first presenting sign of the disease [26] and the overall prevalence of the ocular involvement in patients with COVID-19 was 5% [16]. Furthermore, the ocular involvement of the disease has been reported to be as high as 31.6% [18].

The ocular manifestation was earlier than the systemic manifestation in around a quarter of COVID-19 patients with ocular manifestation regardless of the severity [16]. However, the association of the presence of ocular manifestation with disease severity is yet to be determined due to controversial results from different studies. Furthermore, the same meta-analysis showed that one-third of ocular samples (28%) showed SARS-CoV-2 PCR positivity [16]. Therefore, since coronaviruses could be transmitted to the nasopharynx via nasolacrimal duct and tear positivity can be observed in asymptomatic patients, eyes could potentially be the windows to the COVID-19 transmission.

Being healthcare workers, elderly patients (> 60 years), frequent touching of the eyes with hands, lacrimal duct abnormalities, immunosuppression, and swimming are among the reported possible predisposing factors for ocular manifestation of COVID-19 [16].

The ocular manifestation of the disease can be observed together with, before, or after the systemic manifestations. Ocular manifestation in form of conjunctivitis can be the only presenting symptom of the disease [26]. Therefore, all patients who were admitted to the emergency or ophthalmology departments should be investigated for COVID-19 related findings.

The ocular manifestation of the disease improved in all patients reported in the previous studies and did not get worse in time. Therefore, although red eyes in COVID-19 patients should be accepted as ocular involvement of the disease as conjunctivitis until proven otherwise, emergent referral or consultation of the patients to an ophthalmologist may not be needed.

After an autopsy study reporting SARS-CoV-2 positivity in retinal biopsy specimens of three specimens out of 14 COVID-19 patients [27], retinal involvement of the disease started to be questioned. An optic coherence tomography study showed hyper-reflective lesions at the level of ganglion cell and inner plexiform layers [11]. However, this finding became

controversial due to many consequent correspondences about this study. Rare neuro-ophthalmic presentations such as cranial nerve palsies, ophthalmoplegia, diplopia, and nystagmus have also been reported in patients with COVID-19 [12, 13].

CONTROL MEASURES FOR THE OPHTHALMOLOGICAL EXAMINATION AND SURGERIES

Since the risk of human-to-human transmission increases closer than 1.5 m distance, the waiting area for the patients should be designed to ensure social distancing between patients by blocking alternating seats (Figure 1).

Figure 1. Blocked seats to provide social distancing in the waiting area for the patients.

Because SARS-CoV-2 can live on the inanimate surfaces up to 9 days [28], efficient cleaning of all areas with possible contamination should be disinfected regularly with appropriate disinfectants. Povidone-iodine, a combination of chlorhexidine with ethanol and cetrimide, most alcohol-based solutions such as ethanol or isopropanol significantly reduces the viral titers and is recommended [29,30]. The Centers for Disease Control and Prevention (CDC) specifically recommended the use of alcohol solutions with at least 70% alcohol and diluted household bleach (five tablespoons of bleach per gallon of water) [31]. Some antiseptics-disinfectants formulated with only phenolic or quaternary ammonium compounds, or a combination of chlorhexidine with cetrimide may be ineffective against SARS-CoV-2, therefore should not be preferred for disinfection [32].

Ophthalmic lenses contacting eyes should be disinfected with 1:100 sodium hypochlorite or 3% hydrogen peroxide for 5 minutes followed by washing with water before the next use [33].

Due to the high frequency of fever in COVID-19 patients, all patients admitted to the ophthalmology department should be checked for their body temperature. Patients with an ocular emergency with fever should be examined in an isolated room, but those without any ocular emergency should be referred for COVID-19 exclusion to the relevant department and their ophthalmological examination should be postponed. Patients without fever should also be questioned about COVID-19 related symptoms or risk factors including the history of traveling abroad within the past 2 weeks or any suspicious contact with a COVID-19 patient.

The current recommendation from WHO for general ophthalmology patients would be wearing personal protective equipment according to standard precautions, which is wearing surgical masks in all areas. A complete ophthalmological examination usually takes around 30 minutes. Thus, longer exposure of the ophthalmologists to patients leads to another risk factor for the disease transmission. The distance during the slit lamp examination between

patient and examiner varies between 20 and 40 cm. Therefore, a large protective transparent plastic shield should be installed on the biomicroscopes to provide another control measure during slit-lamp examination (Figure 2).

Figure 2. The close proximity of an ophthalmologist to a patient during slit-lamp examination with appropriate personal protective equipment.

Since the tear can be SARS-CoV-2 positive even without any ocular or systemic finding of the COVID-19 and asymptomatic COVID-19 patients were reported to be 15.6% among all patients [34], ophthalmologists should accept all patients as possible infection sources. Therefore, ophthalmologists should wear protective goggles, N95 masks, and gloves during the examination of all patients to prevent disease transmission. While the American Academy of Ophthalmology recommended ophthalmologists to wear masks and eye protection when caring for patients with potential COVID-19 positivity [35], a report from Hong Kong during the SARS-CoV outbreak recommended the use of personal protective equipment (PPE) including the gloves for all patients regardless of SARS status [36]. The patients can be requested to speak less frequently during the examination.

Studies have shown that healthy individuals touch their eyes 10 times per hour [37]. The use of glasses may be protective against this frequent touching. Interestingly, extended daily use of glasses for more than 8 hours per day was shown to be associated with less susceptibility to COVID-19 emphasizing the importance of wearing protective goggles or glasses [38].

Ophthalmologists preferring not to wear gloves should wash his/her hands with disinfectants after each patient and the ones who prefer to wear gloves should change the gloves after each patient. Ophthalmologists should wear isolation gowns while examining the COVID-19 positive or suspicious patients in an isolated room.

The working shifts of all medical staff can be designed to work as small groups to prevent cross-infection between different staff members. To prevent disease spread among medical staff, all meetings should be made as online meetings. The personnel should also be careful about social distancing. Gathering in large groups of more than 10 people should be stopped.

Outpatient and inpatient ophthalmology care should be separated to curtail the risk of cross-infection. Inpatients should be examined at the bedside with portable devices or in an examination room designed only for inpatient use [39].

Recommendations for each subspecialty clinics in ophthalmology are given below under separate subtitles.

Retina

Retina clinics are usually very crowded, and the patient population usually consist of elderly patients. Therefore, some control measures should be administered to decrease the number of unnecessary visits. The physicians should check the patient records to postpone some of the appointments and the patients should be informed via text messages, phone calls, or emails. Implementation of telemedicine applications could also be helpful for virtual visits to determine the emergency status of the condition. During the fundus examination of the patients, indirect ophthalmoscopes can be preferred instead of slit lamp fundus examination.

Figure 3. Oculoplasty surgery with appropriate personal protective equipment.

Patients necessitating intravitreal injections are a major concern for retina specialists. One approach could be increasing the time interval between the injections. Another approach could be the decision of injection only according to the OCT imaging results. The last approach could be postponing any visits or injections until the patient complains about any significant visual loss.

Oculoplasty

Oculoplasty is a subspecialty of ophthalmology with particularly higher-risk for transmission of COVID-19 compared to the other ophthalmologists and other physicians due to the higher viral load in the nasal cavity than in the throat. Oculoplastic surgeons operate on the nasolacrimal area (lacrimal drainage system and sinuses) as well as the orbit and sinuses, they are at risk for aerosolization of viral particles from nasal mucosa and/or other mucosal surfaces [40, 41]. Therefore, protective face shields or goggles should be used during the oculoplastic surgeries (Figure 3).

Contact Lens

During the contact lens clinics' daily routine, ophthalmologists prescribing the contact lenses and contact lens nurses advising the contact lens use are in close contact with the patients. Therefore, special precautions must be taken to prevent any contamination of the equipment and working environment. Application of the contact lens should be accepted as an elective procedure and patient triaging including the COVID-19 risk assessment and the determination of the emergency status of the contact lens users must be done before accepting the patient appointment.

For former contact lens users, any newly developed complaint should be evaluated via telemedicine or clinic visits and control visits should be postponed. British Contact Lens Association recommended postponing the new contact lens examinations.

Since a study showed that extended daily use of glasses more than 8 hours per day was associated with less susceptibility to COVID-19 [38], contact lens users should be recommended the use of glasses during the pandemic for better protection against COVID-19.

Uveitis

Some uveitis patients are under immunomodulatory treatment possibly making them more susceptible to COVID-19. However, the uveitis patients should not be advised to stop their treatment since the treatment discontinuation may lead to more dangerous conditions. Telemedicine, especially evaluation with fundus photography, can be used for the diagnosis of uveitis. However, all active uveitis conditions should be examined by the physician, but the follow-up interval can be longer than usual.

The current recommendation for immunosuppressive treatment includes the continuation of the treatment apart from the patients with high COVID-19 risk and avoiding the use of

high-dose steroid treatment. Because steroid use of more than 10 mg/day was shown to be associated with a higher hospitalization risk for COVID-19 patients. Interferon and tocilizumab are highly recommended to be continued in the treatment of uveitis patients due to their possible positive effect on COVID-19 treatment. However, the use of anti-tumor necrosis factor treatment in uveitis patients is controversial [42–44].

Cataract

Cataracts are the second most common cause of treatable visual impairment globally. Since cataract surgeries are among the elective surgeries except for some relatively urgent conditions (phacolytic glaucoma, phacomorphic glaucoma, etc.), almost all cataract surgeries were canceled or postponed due to the COVID-19 pandemic. However, the increased cataract patient volume will be a big concern for the future practice of the ophthalmologists.

Some countries recommended the ophthalmologists to start some elective surgeries including cataract surgery. However, precautions should be taken to prevent cross-infection by wearing appropriate PPE including an N95 mask and protective goggles during the surgery (Figure 4).

Figure 4. Cataract surgery with appropriate personal protective equipment including an N95 mask, gloves, and protective goggles.

Cataract surgery training for ophthalmology residents was also impaired. Wet labs can be a useful tool for the training of the residents during the pandemic.

Cataract surgery may have the potential of aerosol formation. A recent study showed that aerosol formation can be reduced with hydroxypropyl methylcellulose (HPMC) coating of the cornea every 1 minute or when 2.2 mm phaco tip was used instead of 2.75 mm [45]. On the other hand, povidone-iodine is used for surgical antisepsis before the cataract surgery and is virucidal to SARS-CoV-2 [46]. Furthermore, phacoemulsification cataract surgery occurs in a closed system preventing the intraocular fluid to contact with the outer environment [45]. However, the safety of the cataract surgery with phacoemulsification regarding the COVID-19 transmission is still unknown.

Cornea

Foreign bodies that necessitate removal, active keratitis, corneal ulcers, corneal perforation, or melt, corneal graft rejection are among the corneal pathologies requiring a visit to the ophthalmology clinic. Elective surgeries including keratoplasties should be postponed. However, therapeutic tectonic keratoplasty can be performed in urgent conditions. The donors should also be checked for COVID-19 before the harvesting process. Theoretically, due to the presence of ACE2 in cornea epithelium, the viruses can be transmitted via corneal transplantation. However, further postmortem studies on corneal tissues should be conducted to better understanding the possibility of transmission via transplantation.

The use of cauterization during ocular surface-related surgeries possess a risk for aerosol formation. Therefore, irrigation will be important during cauterization and the use of cautery should be minimized in terms of power and duration. The smoke should also be evacuated effectively during cauterization.

Glaucoma

Glaucoma is an incipient disease causing painless peripheral vision loss due to progressive optic nerve damage. The well-known risk factor for the disease is increased intraocular pressure. Non-contact tonometer sprays a gas for measuring the intraocular pressure and possibly creates aerosol around that local area for a long time (3-8 hours) thereby creating a possible environment for the disease transmission [47]. Therefore, for safer intraocular pressure measurement, an applanation tonometer with efficient cleaning or iCare tonometer should be used instead of a non-contact tonometer.

Glaucoma patients can be followed only with OCT-RNFL imaging or visual field test to postpone clinical visits. Home-based IOP monitoring with contact lenses can be used for investigating the diurnal variation.

Pediatric Ophthalmology

Sight threatening conditions such as retinopathy of prematurity, congenital cataract, congenital glaucoma, or severe amblyopia can be followed and managed without postponing

any visit to prevent any permanent visual loss. Telemedicine can be used for the follow up with more benign conditions such as strabismus.

Surgery

Hospitalization should be approved only for the SARS-CoV-2 negative cases. However, in conditions requiring urgent intervention such as corneal rupture, the operation can be done without waiting for the PCR test result.

PCR tests should be implemented in all patients before their surgery. For the procedures possibly not causing any aerosol formation, wearing only a surgical mask for the patient can be enough. However, we recommend the use of N95 masks for all ophthalmological interventions.

COVID-19 positive patients should be operated in operating rooms with negative pressure, if possible. Hospitals should provide operating rooms with negative pressure given the possible long duration of the pandemic. The frequency of air change should be high in standard operating rooms. All patients should wear surgical masks.

COVID-19 AND TELEMEDICINE IN OPHTHALMOLOGY

Telemedicine is a way of transmitting any information to support healthcare by using communication technologies. Video examination visits can be used during the pandemic to postpone any elective case or to determine the emergency status of the patient. However, the limitations and medicolegal concerns of virtual visits should be understood by the eye care provider and explained in detail to the patients.

CONCLUSION

In conclusion, ophthalmologists are at increased risks for COVID-19 because of their close physical proximity to the patients during the eye examination. All eye care providers should take precautions against COVID-19 by wearing appropriate PPE including protective goggles, gloves, and N95 masks. Social distancing in outpatient clinics should be warranted for preventing cross-infection. Elective surgeries should be postponed, and only relatively urgent cases should be seen in the clinics. Telemedicine applications should be implemented for patient triaging or virtual visits. Conjunctivitis can be the presenting sign of COVID-19 as well as it can be observed concurrently with the other symptoms. Therefore, all patients with red eyes can be accepted as COVID-19 conjunctivitis until proven otherwise during the pandemic.

ABSTRACT

The purpose of the present chapter is to explain the impact of coronavirus disease 2019 (COVID-19) on diabetes and implications for treatment. The SARS-CoV-2 outbreak affected millions all around the world and the number of infected cases is still increasing. The available scientific data from clinical studies of COVID-19 show that is worse with comorbidities such as diabetes. According to statistical data, the mortality rate in diabetic patients is higher than non-diabetics. SARS-CoV-2 can cause acute diabetes using angiotensin-converting enzyme-2 (ACE-2), which is abundant in Langerhans islets. Anti-diabetic drugs during COVID-19 may be a novel strategy to reduce virus entry and replication in individuals with or without type II diabetes. Studies to date have shown that some drugs tried in the treatment of COVID-19 improve glucose profile but the others cause impairment of glucose metabolism and β -cell function. Dipeptidyl peptidase 4 (DPP-4) inhibitors may prevent the progression of the hyperinflammatory state associated with COVID-19. Therefore, since it is important to maintain glucose homeostasis in COVID-19 treatment, more studies are needed on the hyperglycemia or hypoglycemia molecular mechanisms of anti-diabetic drugs. Telemedicine or digital medicine plays a crucial role in monitoring glycemic control in diabetic patients with COVID-19.

Keywords: COVID-19, diabetes, hyperglycemia, ketoacidosis, anti-diabetic therapeutics

INTRODUCTION: SARS-CoV-2 AND DIABETES

Diabetes, a metabolic disease, characterized by inappropriately raised blood glucose concentrations. Diabetes can be categorized as type I diabetes, type II diabetes, gestational diabetes, and specific types of diabetes due to other causes. The two major types of diabetes are type I diabetes and type II diabetes, which are caused by absolute insulin deficiency (type I diabetes) and/or insulin resistance (type II diabetes). Type I diabetes is caused by the destruction of the pancreatic β -cells and is found in children and adolescents, while type II diabetes results from an imbalance between insulin sensitivity and insulin levels and commonly present in older adults. Type II diabetes also called “adult-onset diabetes”, accounts for approximately 90-95 % of all diabetic individuals. A combination of genetic and lifestyle is involved in the development of type II diabetes. For example, middle-aged and older adults can have prolonged hyperglycemia due to poor lifestyle and an unhealthy diet [1].

According to the International Diabetes Federation (IDF), 1 in 11 people aged 20-79 years worldwide has diabetes in the global population. It has been estimated that the prevalence of diabetes will increase from 463 to 578 million by 2030. Unfortunately, the number will jump to 700 million by 2045. Furthermore, diabetes is among the top 10 causes of death [2]. Thus, the disease is a serious growing problem for global health.

Currently, a new coronavirus, rapidly spreading, remains a threat to most of the human population worldwide. The new virus, SARS-CoV-2, which induce the COVID-19 disease in humans, first appeared in China. One of the coronaviruses (CoVs), SARS-CoV-2, belongs to the large *Coronaviridae* family. It is known that these CoVs, a large family, are enveloped viruses with a single-strand, positive-sense RNA genome. Despite a long history of coronavirus research starting in the 1930s, with the first appearance of SARS-CoV in 2002, many scientists have realized the potential for this virus group to cause fatal infections in humans [3]. It is reported that seven types of CoVs can infect humans [4]. Human coronaviruses (HCoVs), respiratory pathogens, cause respiratory infections such as severe acute respiratory syndrome-CoV (SARS-CoV), and the Middle East respiratory syndrome-CoV (MERS-CoV) [5].

According to the latest data, the COVID-19 outbreak has caused over 1.839.660 deaths and 83.910.386 infected cases and these numbers are increasing [6]. Li et al., [7] reported that angiotensin-converting enzyme-2 (ACE-2) is a functional receptor for SARS-CoV and it infects humans through this receptor. After ACE-2, dipeptidyl peptidase 4 (DPP4) has been identified as a receptor for coronaviruses. One of the highly pathogenic CoV, MERS-CoV uses DPP4 as a cellular receptor [8]. To infect humans, SARS-CoV-2 is also used the ACE-2 cell receptor [9].

Recent evidence has presented that patients with underlying metabolic conditions of diabetes show higher morbidity and mortality than individuals without diabetes [10]. It has been reported that blocking the renin-angiotensin system (RAS) with ACE inhibitors or angiotensin II receptor blockers reduced the development of diabetes in adults [11]. On the other hand, these therapeutics upregulate the ACE-2 receptor on the surface of the host cell and so, the SARS-CoV-2 virus can enter the host cells [12]. This suggests that individuals with diabetes are more likely to be infected with SARS-CoV-2 compared to healthy humans. On the contrary, diabetes disease does not cause an increase in the risk of SARS-CoV-2

infection but may contribute to worsening the outcome of COVID-19 disease [13]. Another thought is that the anti-viral drugs used cause deficiency in glucose metabolism and other endocrine disorders, and even cause ketoacidosis [14, 15].

HYPERGLYCEMIA IS A RISK IN COVID-19

There is an association between hyperglycemia and elevated risk of mortality in stroke, pneumonia, acute myocardial infarction, trauma, and surgery [16]. Hyperglycemia was shown as a risk factor of morbidity and mortality in SARS and MERS [17, 18].

The fact that type II diabetes is the second most common comorbidity of COVID-19 is evidence that these two outbreaks are related. According to the study on adult patients with COVID-19, patients with diabetes disease have a higher probability of in-hospital death compared with non-diabetics [19]. In a study of 7337 COVID-19 patients, 952 of whom had diabetes, it was reported that type II diabetes significantly increases the risk of medical interventions and mortality. However, among the individuals with type II diabetes, patients with well-controlled blood glucose regulation (3.9 to 10.0 mmol/L) were found to perform better compared with patients with poorly controlled blood glucose (> 10.0 mmol/L) [20]. Deng et al., [14] suggested that the prevention of diabetes can contribute to reducing COVID-19 mortality. It is reported that high glucose not only damages cells and tissues but also activates interferon regulatory factor 5 (IRF5), thereby promoting cytokine storm (CS) caused by a virus [14, 21]. Furthermore, it is predicted that SARS-CoV-2 infection induces the CS as a systemic immune response. The CS can cause the progression of the disease and lead to multiple organ failure or even death [22]. Due to the CS caused by high blood glucose and SARS-CoV-2, it is estimated that patients with diabetes have a higher mortality rate.

COVID-19 ON THE REGULATION OF BLOOD GLUCOSE

Some non-diabetes-related diseases, such as systemic inflammation response syndrome, traumatic brain injury, and severe sepsis tend to have high blood glucose levels [23]. This condition is defined as stress hyperglycemia (glucose value > 7.8 mmol/L or 140 mg/dl). Stress hyperglycemia was frequently found in patients not diagnosed with diabetes [24]. Stress hyperglycemia may be occurred as a result of insulin deficiency, worsening of insulin resistance, and increased hepatic glucose production [25]. Similarly, it is thought that COVID-19 patients may also have stress hyperglycemia. The importance of well-controlled blood glucose in COVID-19 patients was reported in recent studies. Wang et al., [16] emphasized that fasting blood glucose at admission is a significant factor for the prognosis of COVID-19. They suggested that the rise of fasting blood glucose elevates the incidence of in-hospital complications. Therefore, since most COVID-19 patients tend to glucose metabolic disorders, glycemic control is significant for all COVID-19 patients, even without pre-existing diabetes. According to another study, in 29 of 184 patients, SARS-CoV-2 infection caused new and permanent hyperglycemia. Thus, the dysregulation of glucose metabolism in patients may be induced by the SARS-Co-2 infection and, this increases the development of severe COVID-19 in patients [26]. On the contrary, Liu et al., [27] specified that a high level

in admission fasting blood glucose was not a dependent risk factor for developing critical diseases of COVID-19 patients. They suggested that fasting blood glucose may be associated with systemic inflammatory reactions and immune status. Continuous glucose monitoring may prevent infections and complications, thereby contributing to the recovery of the patient with COVID-19. According to Li et al., [28], under the persistent hypoxia state hyperglycemia can develop in the COVID-19 patients. They also recommended that to prevent the progressive COVID-19 from getting worse, adequate oxygen intake for patients are monitored, as well as blood glucose levels.

PANCREAS FAILURE

The pancreas is an important gland in diabetic patients as well as in patients with COVID-19. Recent studies have reported that patients with COVID-19 show not only fever and respiratory disease but also an increasing number of patients with gastrointestinal symptoms such as nausea, vomiting, and abdominal pain [29]. Hadi et al., [30] reported that acute pancreatitis is a complication related to COVID-19. The researchers emphasized that if patients with COVID-19 suffer from abdominal pain, lipase and amylase should be measured. In a study on 52 patients with Covid-19, 17 % of COVID-19 cases showed pancreas injury that was defined as increased lipase [31]. Ding et al., [32] reported that SARS-CoV was found not only in the lung, liver, intestine, and kidney tissues but also in the pancreas. Thus, the pancreas may be a potential target of SARS-CoV infection. Consistent with the report of Ding et al., [32], the high damage level of SARS-CoV in the pancreas is correlated with ACE-2 expression in the pancreas. Moreover, ACE-2 expression is localized especially in the endocrine part of the pancreas. SARS-CoV may enter Langerhans islets using ACE-2, the receptor of SARS-CoV, and it may cause acute diabetes after damaging the islets [33]. According to Wang et al., [31], the pancreatic damage in COVID-19 may be induced directly by the cytopathic effect mediated by SARS-CoV-2 replication. Indirectly, the damage in the pancreas may be originated from immune-mediated and systemic inflammatory cellular responses induced by SARS-CoV-2 infection. Researchers found that the expression of ACE-2 in the pancreas of healthy individuals is slightly higher than in the lungs. Similar to SARS-CoV, SARS-CoV-2 may also bind to ACE-2 in the pancreas and enter into the tissue. Therefore, SARS-CoV-2 causes damage to the pancreas. Moreover, the expression of ACE-2 has been shown in both the exocrine and endocrine regions of the pancreas [34]. In the same study on 121 cases with COVID-19, the authors found an increase in amylase and lipase levels depending on the severity of the disease. It was emphasized that more attention should be paid to the pancreas in patients with SARS-CoV-2 infection, particularly, in severe cases. Otherwise, it has been suggested that there may be pancreatic injuries associated with the use of antipyretic drugs [31].

DIABETIC KETOACIDOSIS

Diabetic ketoacidosis (DKA), one of the most serious complications of diabetes, is characterized by the triad of hyperglycemia (blood glucose level > 13.9 mmol/L), acidosis

(arterial pH less than 7.3 and serum bicarbonate level less than 18 mEq/L) and ketosis (ketonemia or ketonuria) [35].

DKA has been noticed in COVID-19 as well as in other serious infections [36]. DKA can be triggered by SARS-CoV-2 in poorly controlled diabetic patients [10]. In a case study, researchers reported that COVID-19 could cause DKA and multiorgan failure even without lung involvement in patients with diabetes [37]. Similarly, Chee et al., [38] found that DKA may be occurred by SARS-CoV-2 in a 37-years-old male diabetic patient. In the period from January 1 to March 3, 2020, a Chinese cohort study on 658 patients was reported that COVID-19 infection may cause ketosis and ketoacidosis in non-diabetic individuals, and can induce DKA in diabetic patients [39]. According to another case study, in a 54-years-old male patient with newly diagnosed diabetes, COVID-19 infection may cause an increase in DKA [40]. When SARS-CoV-2 enters pancreatic islet cells, it damages β -cells, which may induce precipitated DKA in patients.

ANTI-DIABETIC THERAPEUTICS

According to the last International Diabetes Federation (IDF) atlas, the control of blood glucose is usually initiated with metformin as a first-line drug. In cases where treatment with a single anti-diabetic drug is not sufficient, there are combination treatment options such as sulfonylureas, DPP4 inhibitors, glucagon-like peptide 1 (GLP-1) analogs. Insulin injections may be needed if oral anti-diabetic drugs are unable to control hyperglycemia [2].

Studies have shown that some of the drugs tried in the treatment of COVID-19 improve glucose profile, but some drugs cause impaired glucose metabolism [41]. On the other hand, although ACE-2 and DPP4, two coronavirus receptor proteins, are known to be important in the regulation of glucose homeostasis and inflammation, there is insufficient clinical evidence that drugs targeting these receptors benefit human coronavirus infections [42]. One study suggested that ACE inhibitor (ACEI) and angiotensin receptor antagonist (ARB) use should be considered in diabetic patients during the COVID-19 outbreak, while another study reported that the use of ACEI and ARB in diabetic patients may increase the morbidity and mortality of COVID-19 [43, 44].

The potential benefits of anti-diabetic drugs during COVID-19 are as follows.

METFORMIN

Metformin, which has been used for decades, is the most preferred drug worldwide for every diabetic patient. Jean Sterne introduced this drug as ‘Glucophage’, which means ‘glucose eater’, in 1957 [45]. Interestingly, Sharma et al., [46] suggested that when there is no specific agent against COVID-19, metformin should be among the drugs used to fight the virus. Rena et al., [47] have mentioned that metformin affects the improvement of glucose metabolism through the AMP-activated protein kinase (AMPK) dependent mechanism. Metformin is thought to provide conformational and functional changes to the ACE-2 receptor through AMPK activation that causes phosphorylation of ACE-2. As a result, binding of SARS-CoV-2 to the receptor-binding site can be prevented, so that the virus is not

able to enter the cell [46]. By contrast with Sharma et al., [46], the researchers have suggested that metformin may promote SARS-CoV2 infection by increasing the presence of ACE-2 in the respiratory system. On the other hand, researchers still not sure whether metformin is friendly or not [48]. According to a retrospective study on 283 patients by Luo et al., [49], the fasting blood glucose level in diabetic patients infected with COVID-19 using anti-diabetic drugs other than metformin was lower than in those using metformin. However, other laboratory parameters were similar in patients taking metformin and other anti-diabetic drugs. This study also suggested that the mortality of metformin users was lower than that of non-users in diabetic patients infected with COVID-19.

DIPEPTIDYL PEPTIDASE 4 (DPP4) INHIBITORS

DPP4 inhibitors are commonly used to control glucose in patients with diabetes [42]. To facilitate virus entry, SARS-CoV-2 uses co-receptors as ACE-2 partners. DPP4, a membrane protein, has also been reported among these co-receptors [50]. It has been reported that DPP4 inhibitor anti-diabetic drugs such as gliptins (sitagliptin, vildagliptin, or linagliptin) can prevent coronavirus / DPP4 interaction and thus protect the cell from virus entry [51]. Consistent with this study, Solerte et al., [52] suggested that the inhibition of DPP4 may be a new strategy to strengthen COVID-19 therapy in diabetic patients or not. Besides, DPP4 inhibitors may also be used to prevent the progression of the hyperinflammatory condition associated with COVID-19, thanks to its inflammatory healing properties [53]. In a review article by Bassendine et al., [54], it was emphasized that DPP4 activity is higher in elderly individuals and the increase of DPP4 in plasma is an indicator of the onset of metabolic syndrome. Thus, gliptins used in DPP4 inhibition may be a treatment strategy to reduce the severity of COVID-19 disease.

GLUCAGON-LIKE PEPTIDE 1 (GLP-1) RECEPTOR AGONISTS

GLP-1 receptor agonists, which are more widely used in the treatment of diabetes in recent years, reduce cardiovascular risk [55]. Beyond their anti-diabetic effects, GLP-1 receptor agonists have anti-inflammatory effects [56]. Thus, Ceriello et al., [57] suggested that GLP-1 receptor agonists might be useful in COVID-19 patients due to their anti-inflammatory effects. Similarly, Longo et al., [58] also reported that GLP-1 receptor agonists could be used in diabetic patients with COVID-19 due to their glucose-lowering and anti-inflammatory effects. However, they suggested that data on the use of GLP-1 receptor agonists in these patients were insufficient.

SULFONYLUREAS AND THIAZOLIDINEDIONES

Sulfonylureas and thiazolidinediones provide excellent improvements in glycemic control in different mechanisms. Sulfonylureas stimulate insulin secretion and act immediately on HbA1c, whereas thiazolidinediones sensitize insulin and take longer to express their effect

[59]. According to Derosa and Maffioli [60], thiazolidinediones may provide a more adequate control in diabetic patients compared to sulfonylureas due to their cardiovascular risk lowering effect. Sulfonylureas have been reported to show no interaction with ACE-2 and its use can be safely continued [61].

It has been reported that sulfonylurea treatment affects the risk of hypoglycemia in diabetic patients with COVID-19 [62]. Thiazolidinediones treatment may reduce the development of pulmonary fibrosis (PF) in patients with COVID-19 and thus be a valuable approach to alleviating the course of the disease, especially in diabetic patients. However, due to insulin sensitivity, it is recommended that diabetic patients be followed carefully for any signs of hypoglycemia [63]. Other than these features, thiazolidinediones have anti-inflammatory properties through PPAR- γ activation and affect severe viral pneumonia [64].

INSULIN

To control glucose in hospitalized diabetic patients, insulin treatment has been used extensively for decades. Some case studies have shown that intravenous insulin administration accompanies anti-viral agents and empirical antibiotics for the treatment of both COVID-19 and DKA [10,37]. According to Nakhleh and Shehadeh [65], there is a relationship between SARS-CoV-2-induced lung injury and hyperglycemia. Researchers defend that insulin can be promising in the treatment of COVID-19 patients, thanks to its immunomodulatory effect, its ability to prevent the spread of cytokine storm and lung damage by regulating ACE-2 expression and angiotensin II levels, and its ability to reduce the risk of developing DKA or hyperglycemic hyperosmolar states. Similarly, in a study conducted on 59 patients with COVID-19, it was stated that insulin therapy could be an effective method to control glycemic targets and reduce mortality [66].

SODIUM GLUCOSE TRANSPORTER-2 (SGLT-2) INHIBITORS

Current guidelines for the management of type II diabetes recommend SGLT-2 inhibitors can use in patients with type II diabetes and heart failure to reduce heart failure, major adverse cardiovascular events, and cardiovascular disease death [67]. However, according to the study by Hamblin et al., [68], the use of SGLT-2 inhibitors has been associated with an increase in DKA. In the study, it was observed that SGLT-2 inhibitor users were more likely to develop DKA than non-SGLT-2 inhibitor users. In the same way, Orioli et al., [69] also recommend discontinuation of SGLT-2 inhibitors in patients with serious forms of COVID-19 because of the risks of ketoacidosis and lactic acidosis. On the other hand, it is predicted that the careful use of dapagliflozin, an SGLT-2 inhibitor, and insulin together avoiding dehydration in COVID-19 may be beneficial in the treatment of diabetes [70].

CONCLUSION

Diabetes plays a significant role in further deterioration of the clinical severity of COVID-19. It is a fact that blood glucose levels should be monitored regularly in COVID-19 patients. Unfortunately, the impact of anti-diabetic drugs on COVID-19 outcomes remains unclear. It is important to investigate how SARS-CoV-2 interacts with glucose metabolism to understand disease pathogenesis and improve treatments.

Chapter 464

THE IMPACT OF COVID-19 PANDEMIC ON THE PATIENTS WITH CHRONIC RESPIRATORY DISEASES

Buket Caliskaner Ozturk*, MD

Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty,
Department of Pulmonology, Istanbul, Turkey

ABSTRACT

The process beginning with some cases of pneumonia of unknown etiology in the city of Wuhan in China at the end of 2019 has continued with the agent being defined as a new virus and announced as a pandemic by World Health Organization (WHO). It has been seen to spread by droplet route and direct contact and usually locate to and cause disease condition in the respiratory tract. It may present asymptotically or cause a clinical presentation ranging from mild upper respiratory tract infection to adult respiratory distress syndrome due to viral pneumonia. The clinical condition it causes has been named *coronavirus disease 2019 (COVID-19)*.

The first impressions on the disease have shown that the disease caused by this new type of virus presents with higher rates of mortality and morbidity in the elderly patients with several co-morbidities including cardiovascular conditions, immune suppressive diseases, metabolic, and chronic respiratory tract diseases. In the initial phase of the pandemic, it has been predicted that the presence of an underlying chronic respiratory tract disease may cause serious co-morbidity because the disease involves the respiratory tract particularly. In the forthcoming period, it has been found that cardiovascular and metabolic diseases might cause more severe co-morbidity compared to respiratory tract diseases.

Chronic respiratory tract diseases that may lead to serious co-morbidity during the pandemic include chronic obstructive and restrictive respiratory tract diseases, and respiratory sleep disorders.

The first and most important recommendation for patients with chronic respiratory tract diseases should be protection and the precautions. Concern on this point is whether the inhaler and systemic steroids used in the treatment of chronic obstructive pulmonary disease (COPD) and asthma are an extra risk factor. While research on this topic

* Corresponding Author's Email: drbuketozturk@gmail.com.

continues, it has been recommended that the patients should continue their treatment as always because no data exists suggesting that they increase the risk. Thus, it has been aimed to maintain stabilization of the disease, decrease hospital exposure, and reduce the risk of COVID-19 contamination. Pulmonary rehabilitation should be recommended to these patients in this process.

The similarity between the radiological findings of COVID-19 and interstitial pulmonary diseases is of importance in the differential diagnosis. Additionally, the patients with COVID-19 are a candidate to be a patient with interstitial pulmonary disease because fibrosis may occur in the recovery process of the disease.

Patients with obstructive sleep apnea syndrome (OSAS) also have several cardiovascular and metabolic disorders. Thus, OSAS is an extra high-risk factor for COVID-19. Furthermore, positive airway pressure (PAP) devices used in its treatment are additional important threats because they spread aerosols.

Keywords: COVID-19, chronic respiratory diseases, pandemic

INTRODUCTION

A virus that emerged in Wuhan city of China in December 2019 and was found to be originating from the livestock market has spread among the humans and caused a pandemic. The virus named Severe Acute Respiratory Syndrome-Coronavirus-2 (SARS-CoV-2) spreads by route of the droplet or direct contact.

With the emergence of the first cases, it was observed that SARS-CoV-2 was characterized by the upper and lower respiratory tract infection in particular and presented with more severe clinical courses especially in the elderly, immune-suppressive, and with co-morbid patients. It utilizes the receptors of angiotensin-converting enzyme-2 (ACE-2) for entering the cells. ACE-2 receptor is a protein present on the cell surface. It is most abundantly present in the lungs, heart, blood vessels, kidneys, liver, and gastrointestinal tract [1]. The virus binds to the ACE-2 receptor via the spike protein on its surface. The nasal mucosa, bronchi, and lung parenchyma all of which have a high degree of expression of ACE-2 receptors are more sensitive to the SARS-CoV-2 virus. Thus, the respiratory tract is frequently involved by the disease.

The primary viral replication is considered to occur primarily and frequently in the mucosal epithelium of the upper respiratory tract including the nasopharynx and then to continue in the lower respiratory tract. It may be asymptomatic or show clinical presentation ranging from mild upper respiratory tract infection to acute respiratory distress syndrome (ARDS) due to viral pneumonia. Although it primarily causes clinical disease of the respiratory tract, it may also involve other systems.

Advanced age and presence of co-morbid conditions are predisposing factors for both infection with SARS-CoV-2 and increased severity of the infection. Especially the conditions such as hypertension, ischemic heart diseases, diabetes mellitus, chronic obstructive lung disease have been reported as the most important risk factors for the severe course of the disease [2–8].

It has been thought that the presence of chronic respiratory tract diseases might be a cause of serious co-morbidity because the virus involves the respiratory tract after it begins to spread. For a virus that may involve the respiratory tract, the presence of underlying

pathology of the respiratory tract will facilitate contamination of the infection as well as it will lead to a worse clinical course. Thus, a high rate of mortality and morbidity is expected in the cases of COVID-19 with chronic lung diseases. Additionally, considering that these patients are elderly, the risk is much higher. Based on the first impressions and data, however, lung diseases have been observed to cause lower risk for COVID-19 compared to other chronic diseases. In a meta-analysis on 1.576 patients with COVID-19, the frequency of hypertension was reported as 21.1%, diabetes mellitus as 9.7%, and cardiovascular diseases as 8.4% whereas the frequency of the lung diseases was reported as 1.5% [8]. Studies are still going on because of the short time from the emergence of the disease.

COVID-19 PANDEMIC AND THE PATIENTS WITH ASTHMA

Asthma is a heterogeneous disease related to hypersensitivity of the airway to the direct or indirect stimulants and is characterized by chronic airway inflammation [9]. Genetic factors usually play role in the development of asthma. Its exacerbations, however, are usually due to environmental factors. The infections and exposure to allergens are leading causes of asthma attacks. The most common infectious causes are viral respiratory tract infections. Virus-related attacks may present with poorer clinical findings, especially in uncontrolled asthma.

During the initial phase of the pandemic, asthma was considered to be an important risk factor for COVID-19 because of its chronic nature as well as its risk of exacerbation. It was also predicted that the inhaler and systemic steroids used in the treatment of asthma might trigger this risk by predisposing to the infections. But surprisingly, the first analyses on COVID-19 revealed that the patients with asthma showed a similar presentation to the general population, and studies were published supporting that asthma was not a risk factor for being contaminated with COVID-19 and for mortality [10–13]. Consequently, a few opinions were suggested for a lower prevalence of asthma than expected in patients with COVID-19.

The first of these opinions was that patients with asthma were protected from the disease because they used medication regularly and because of their conscious behaviors. Although it was expected that long-acting inhaler steroids used in the treatment of asthma might increase this risk, it is also possible that they might decrease the risk because they suppress replication of the coronavirus and the production of cytokines [14]. The studies on budesonide and cyclosonide suggested that these agents had effects of inhibiting HCoV-229E replication and cytokine production in the human nasal and tracheal epithelial cells, that cyclosonide blocked in vitro COVID-19 RNA replication and prevented cytopathic activity of the virus [15, 16]. Data on this topic, however, are limited, and comprehensive and new studies are needed.

The second opinion is that the most common symptoms in COVID-19 are dyspnea and cough, and there was a possibility of missing out on the presence of COVID-19 in the patients with asthma because of the similarity of symptoms. Accuracy of this possibility, however, was weakened after the first impressions on the pandemic. COVID-19 shows different presentations from asthma exacerbations radiologically as well as in terms of laboratory findings. While cough and dyspnea occur in both of them, a sudden increase in dyspnea and wheezing are in the foreground in the asthma exacerbations and sore throat, high fever, anosmia and ageusia, and diarrhea are predominant findings in COVID-19. On the laboratory

findings high level of D-dimer and ferritin, presence of lymphopenia, and radiological view of dispersed viral pneumonia are supportive findings for COVID-19. However, the theory may be validated by confirmation by the studies on the patients with COVID-19 and asthma together.

Another point on the lower prevalence of COVID-19 than expected in asthma may be that prevalence of smoking is lower in patients with asthma compared to the general population. Studies have shown that smoking is an important risk factor for contamination with and poorer clinical course of COVID-19. This may be associated with a lower risk for patients with asthma than that predicted for COVID-19 [17].

Another opinion was that presence of chronic respiratory tract disease might have protected from COVID-19 through a different mechanism. It has been demonstrated that the virus utilizes the ACE-2 for entering the cells. ACE-2 expression is known to be lower or less active in asthma [18], which means protection for patients with asthma from COVID-19.

Even though it has been understood that asthma isn't a risk at the predicted level in patients with COVID-19, SARS-Cov-2 is an important risk factor for exacerbations of asthma similar to other viruses. It may cause severe clinical course in patients with asthma. Thus, the approach that patients with asthma will follow during the pandemic process is of importance. National Institute for Health and Care Excellence (NICE) and Global Initiative for Asthma (GINA) published interim reports to give recommendations on the management of asthma during the pandemic [19, 20]. The main items suggested are as follows:

- To prevent contamination risk of the infection, the patients should be educated on social isolation, keeping the distance, not contacting, hand hygiene, and using the masks correctly.
- Patients with asthma are recommended to continue their current medications during the pandemic; the dose of the inhaler steroids may be increased, if necessary, and lowering the line of medication is not recommended even though asthma is controlled during the pandemic. Discontinuing the disease-modifying drugs or lowering their dose may jeopardize controlling asthma, increase the risk of exacerbation, and consequently may cause the risk of contamination of the virus by leading to presentation to the hospital.
- During the attacks, using short-acting systemic steroids shouldn't be avoided.
- During the attacks, using nebulizers should be avoided because they may spread aerosols; metered-dose inhalers should be preferred and the spacer may be used when necessary.
- Allergic rhinitis is one of the diseases accompanying asthma and its treatment is important in controlling asthma. It is recommended that patients with asthma using nasal steroids for allergic rhinitis should continue their treatment during the pandemic in order not to impair asthma control.
- The pandemic process during which social isolation and time at home are increased has been a disadvantage for the patients with allergy, especially to house dust mites. In contrast, increasing time at home has been an advantage for the patients with allergy to the pollens. Controlling the signs of coughing and sneezing by giving the right patient symptomatic treatment at the right time is of great importance in decreasing the attacks as well as the spread of the aerosols.

- Routine examination of the patients with asthma should be delayed to protect them from exposure to the hospital environment and the virus. Interviews may be done and required recommendations may be given via telephone, internet, e-mail, etc.
- Spirometric tests should be avoided as much as possible. If they should be performed absolutely, all individual protective equipment should be worn by the technician because of asymptomatic and unknown COVID-19. The room should be well ventilated, and it should be carried out in a negative-pressure room, if possible.

Treatment with anti-IgE, anti-interleukin (IL)-5/IL-5 alpha, IL-4-alpha receptor antagonists used to control patients with severe asthma have been reported not to increase the risk for COVID-19. Although it has been recommended that the patients using biological agents should continue their treatment, it is also recommended that these patients should extend the interval between the treatments to decrease hospital exposure [21].

In conclusion, based on the information collected so far asthma is not considered as a factor increasing the risk for COVID-19 although more comprehensive studies are needed to confirm the validity of and discuss reasons for this. COVID-19, however, may be a poor prognostic and exacerbation factor for asthma. Thus, taking measures for protection from the infection as well as giving optimal treatments to control asthma during the pandemic process is considered as the most important factor in patients with asthma.

COVID-19 PANDEMIC AND THE PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

COPD is a disease characterized by irreversible and progressive airway obstruction. This condition develops as a consequence of the inflammatory process to the harmful gases and particles. Being a preventable and treatable disease, COPD presents with exacerbations of which severity and frequency increases in time. It is an important cause of morbidity and mortality in the world. The most common cause of COPD exacerbations is tracheobronchial infections. It is known that these infections are mostly viral.

COPD is considered as a co-morbidity factor for COVID-19. Its prevalence ranges between 1.1% and 2.9% [2, 8, 11]. COPD is a chronic respiratory disease condition although it has a lower prevalence for COVID-19 compared to other co-morbid diseases. Thus, question marks and research are still going on. COPD has been reported to have 5 folds higher risk for severe COVID-19 infection [22]. It may be suggested that this is due to advanced age, inhaler steroid use, structural damage, suppressed immunity, and exacerbations in the patients with COPD. Difficulties in adapting the protective measure due to advanced age in the patients with COPD is another factor increasing the risk of contamination of the infection. A short time from the beginning of the pandemic and the limited number of studies conducted on this topic so far leave controversial areas behind.

The main harmful particle leading to the development of COPD is tobacco. Nicotine, which is present in tobacco causes increased expression of the ACE-2 receptors. This is considered to facilitate entry of the virus to the cell and development of the disease for COPD patients [23, 24].

Differential diagnosis between exacerbations of COPD and COVID-19 may be difficult due to the similarity of the symptoms at the time of presentation. High fever, cough, and dyspnea are present in both of them. In the laboratory findings, a high level of D-dimer and fibrinogen is supportive of COVID-19 although they may be elevated in the patients with COPD due to several confounding factors such as co-morbidity and advanced age and these may not be helpful in the differential diagnosis. Imaging studies may be helpful in the differential diagnosis. Even though findings supportive of COVID-19 may facilitate diagnosis, alterations that may be present in the background of the lung in the COPD such as emphysema, bronchiectasis, peribronchial thickening may overlap with findings of COVID-19 and cause difficulties in diagnosis. At this point, comparative evaluations with the previous radiological examinations may be utilized.

The rate of development of severe disease with oxygen desaturation and rates of admission in the intensive care unit, intubation, and mortality in COVID-19 has been reported to be higher in the patients with COPD. This may be suggested to be related to structural parenchymal disorders of the lung and reduced respiratory function.

The measures that should be taken for patients with COPD are as follows:

- In addition to the rules of social distance and routine hygiene for being protected from the pandemic, extra measures should be taken for the patients with COPD not to encounter the virus. First of these should be delaying routine controls of the patients.
- Several studies exist indicating that the use of inhaler corticosteroids might cause an increased risk of pneumonia in COPD [25]. At the beginning of the pandemic, this was predicted to be an extra risk for COVID-19, and the opinion that using inhaler and steroid treatments will not be appropriate during the pandemic was proposed. However, the Global Initiative of COPD (GOLD) noted that the opinion that use of the inhaler and systemic steroids will not be appropriate during the pandemic of COVID-19 didn't have a scientific basis by publishing an interim report in 2020. It was reported that destabilizing COPD as a consequence of interrupting the treatment would be a higher risk for the patients. The recommendation of the patient with COPD during the pandemic would be continuing the current treatment exactly as usual. Even previously planned interruptions have been recommended to be delayed [26]. It has been recommended to wait until the efficacy of the pandemic will cease to switch the treatment. The main objective during the pandemic is to decrease hospital exposure of the patients by avoiding the exacerbations without destabilizing COPD.
- In the context of pulmonary rehabilitation with a multidisciplinary approach, the patients receive education on nutrition, psychosocial support, regulation of the daily life activities, and exercise. It is appropriate to incorporate a pulmonary rehabilitation support program to the medical treatment in the patients not receiving such supportive treatments because pulmonary rehabilitation will contribute positively to the respiratory reserve and thus, it will provide an advantage in the case of encountering COVID-19.
- Spirometric tests should be avoided in the patients presenting admitted to the hospital in the presence of attacks or symptoms. Assisting devices such as nebulizers, high-

flow oxygen, and non-invasive mechanic ventilators cause the spread of the aerosols and carry a high risk for contamination; their use should be limited as much as possible. In the case of using them for mandatory reasons, negative-pressure rooms should be preferred [27]. NICE guideline for the nebulizers states that the use of the nebulizer by the patients will not be an additional risk factor for contamination because the aerosol comes from the reservoir of the nebulizer and doesn't carry viral particles from the patient [26]. Nonetheless, it would be useful to limit their use as much as possible. Metered-dose inhalers should be preferred instead of nebulizer; spacer may be used. In the case of using nebulizer in the patients not being able to use metered-dose inhalers, the patient should be alone in the room and the room should be ventilated well after their use.

- If it is mandatory to provide non-invasive mechanical ventilator (NIMV) support in the case of problems of limited sources of intensive care bed and available invasive mechanical ventilator, it should be given with a full-face mask with Helmet mask to minimize the risk.
- The procedures should be avoided such as sputum induction and nasotracheal aspiration creating a high risk for contamination of COVID-19 because of the risk of development of aerosols in patients with COPD.

In conclusion, COPD is a risk factor for COVID-19. Risk in COPD, however, is lower compared to other chronic diseases related to other systems (i.e., diabetes mellitus, hypertension) although it is a chronic lung disease. The diagnostic process of the patients is of importance because of the similar clinical presentation of both conditions. As in other chronic diseases, the main objective in patients with COPD should be to protect the patient from the virus. For this purpose, the current treatment should be continued in the usual manner and the dose of the inhaler steroid shouldn't be reduced in order not to destabilize the treatment. Use of the nebulizers, high-flow oxygen, and NIMV should be avoided as much as possible.

COVID-19 PANDEMIC AND THE PATIENTS WITH INTERSTITIAL LUNG DISEASE

Interstitial lung diseases is a common name of diseases presenting with varying degrees of fibrosis, inflammation, and structural alterations in the lung parenchyma and affecting the lungs diffusely. The fact that immune-suppressive agents are usually used for their treatment is a facilitating factor for being contaminated with SARS-CoV-2. Additionally, destruction in the lung parenchyma and reduced respiratory reserve may also cause severe clinical presentation of COVID-19.

Both interstitial lung diseases and COVID-19 have similar clinical and radiological features. Clinically dyspnea, the non-productive cough may be present in both; the presence of fever, sore throat, anosmia and ageusia, muscle pain, and diarrhea should suggest a diagnosis of COVID-19. Radiologically, lesions of ground-glass density may be seen in both diseases. Comparing with the previous images is of importance in distinguishing the new appearing ground-glass lesions.

In COVID-19, apoptosis of the epithelial and endothelial cells occurs in the early periods along with rapid viral replication and increased pro- inflammatory/chemokine responses [28–30], followed by vascular leakage, edema, and uncontrolled inflammatory response [31–34]. In the later periods, these are followed by widespread lung damage, fibrosis in the interstitium and alveolar space, hyperplasia of the pneumocytes, and uncontrolled cellular proliferation. These alterations are accompanied by the abnormal immune response to the viral invasion and consequent imbalance in the increased production of cytokines. During this process, pulmonary epithelial cells and alveolar microvascular endothelial cells become the target organs attacked by the inflammatory mediators and lead to characteristic damage of ARDS.

Tissue injury on one hand and impaired remodeling on the other hand increase mortality. In the patients surviving ARDS develop pulmonary fibrosis. On the other hand, there is a possibility that pulmonary involvement of COVID-19 may heal with fibrotic scar tissue in the patients not developing ARDS. Thus, all patients with COVID-19 are a candidate for interstitial lung disease independent of the development of ARDS. Thus, preventing and treating pulmonary fibrosis may be one of the targets in treating COVID-19. Several options exist to resolve the cytokine storm and inflammatory factors including cytokine inhibiting agents, plasma replacement therapy, and blood/plasma filtration. The long-time effects of these medicines are not known yet.

Recommendations for patients with interstitial lung diseases are as follows [35]:

- First of all, the patients should take measures of using a mask, hygiene, and social distance for protection from the disease.
- Routine controls should be delayed during the pandemic and they should be instructed on that they shouldn't apply to the hospital if they don't have symptoms.
- Respiratory function tests should be avoided even though they are presented to the hospital with new symptoms.
- In addition to the medical treatment, the patients should be recommended pulmonary rehabilitation.
- Idiopathic pulmonary fibrosis (IPF) is an important group of interstitial lung diseases. Anti-fibrotic agents are used for their treatment. Using anti-fibrotic agents for IPF isn't an additional risk for COVID-19. Continuing to use the drugs should be recommended during the pandemic.
- In the case of making a diagnosis of COVID-19 in the patients with IPF using anti-fibrotic agents, the drugs may be discontinued for 4 to 8 weeks; in the case of discontinuation, however, the risk of exacerbation of IPF should be kept in mind and the decision should be tailored on an individual basis.
- Discontinuing medication in patients using immune suppressive therapy may exacerbate the findings of the present disease. There is no consensus on this topic.
- If a patient with interstitial lung disease is diagnosed as having COVID-19, immune suppressive therapy is discontinued during the active infection and then for 2 weeks following the recovery of the disease (or for a longer period if the patient can tolerate). Discontinuing the immune-suppressive treatment should be considered if COVID-19 is detected in patients with interstitial lung disease.

COVID-19 PANDEMIC AND THE PATIENTS WITH OBSTRUCTIVE SLEEP APNEA SYNDROME

OSAS is a condition characterized by a complete or partial obstruction of the upper airway during sleep. It manifests with apnea or hypopnea episodes followed by desaturation and subsequent arousals [36].

OSAS is usually accompanied by cardiovascular and metabolic conditions. Several factors including advanced age, male gender, obesity, hypertension, cardiovascular diseases, and diabetes mellitus make the high risk for both OSAS and COVID-19, increasing the frequency of development of COVID-19 in the patients with OSAS. COVID-19 presents mortality for the group of elderly patients with serious co-morbidities [37].

OSAS is one of the most common chronic respiratory diseases. The presence of quality sleep is of great importance to boosting immunity and for a healthy life. Treatment of patients with sleep apnea is much more important during the pandemic process because they have poor sleep unless they are treated. Thus, measures for the patients with OSAS gain extra importance during the pandemic.

OSAS and obesity have been suggested to worsen clinical course in the patients with coronavirus infection by increasing hypoxemia and cytokine storm.

The most effective therapeutic option for OSAS is PAP. Regularly and appropriately using the treatment during the pandemic is of great importance for quality sleep [38].

In contrast, another opinion exists advocating to discontinue PAP treatment during the pandemic. It suggests that treating the asymptomatic virus-carrying patients with OSAS with PAP at home may contaminate the virus to the household [39]. In this case, considering the risk-benefit ratio, it would be more appropriate to recommend the patients without diagnosis of COVID-19 to continue the treatment during the indeterminate pandemic period. If the patient having a diagnosis of COVID-19 is being followed at home, treatment may be interrupted for 2 weeks to protect the household again considering the risk-benefit ratio.

If the patient with a diagnosis of COVID-19 has been admitted to the hospital:

- It is recommended to discontinue the treatment until the attendant physician allows using PAP [38].
- If a PAP device will be used, it should be used in negative- pressure rooms, or if unavailable in the single rooms in which the health providers use full individual protective equipment [27].
- In the hospital, if the one-circuit device of the patients own will be used and the mask has an expiration valve, changing it with a mask without a valve and mounting a viral/bacterial filter will substantially reduce the risk of droplet contamination [40].

ABSTRACT

Cardiovascular diseases are the leading cause of morbidity and mortality in the world, but with the Corona Virus Disease-2019 (COVID-19) pandemic emerging at the end of 2019, this issue has gained different importance. The presence of cardiovascular diseases leads to more severe COVID-19 infection and an increased mortality rate. On the other hand, COVID-19 itself causes myocardial damage and this contributes to morbidity and mortality. At the beginning of the pandemic, there was a concern that angiotensin converting enzyme (ACE) inhibitors or angiotensin receptor blockers (ARB) would up-regulate the ACE2 receptor at the tissue level, increasing viral binding and facilitating the infection. With the current studies, this opinion has lost the influence and it was decided not to change the treatment of patients using ACE inhibitors or ARBs. Another important point is that patients with cardiovascular diseases are now far from the healthcare they could receive before as both pre-hospital and hospital health care is directed towards the COVID-19 pandemic. Considering that the epidemic will not disappear rapidly, a different arrangement may be planned in healthcare services.

Keywords: cardiovascular disease, COVID-19, coronavirus

INTRODUCTION

The disease caused by “Severe Acute Respiratory Syndrome-Coronavirus-2” (SARS-CoV-2), which is accepted as a global pandemic by the World Health Organisation (WHO), has been named Corona Virus Disease-2019 (COVID-19) [1, 2]. By September 2020, COVID-19 infection affected more than thirty million people and caused nearly one million deaths. SARS-CoV-2 is a highly contagious virus and spreads mainly through droplets and direct contact. The average incubation period is 5.5 days but extension up to 14 days is known [3]. In symptomatic cases, the most common symptoms are fever, fatigue, muscle pain, sore throat, and dry cough, less frequently nausea-vomiting, and diarrhea [4]. It is important not to forget the atypical presentations including delirium, hypothermia, and abdominal pain, especially in elderly patients [5].

SARS-CoV-2 is genetically 79% similar to the SARS-CoV that caused the SARS epidemic between 2002 - 2003 and 96% similar to coronaviruses in bats. The main feature of SARS-CoV-2, thought to be formed as a result of a new mutation, is that the virus causes infection by binding to the human angiotensin converting enzyme 2 (ACE2) receptor, after activation of its spike (S) protein by the transmembrane protease serine 2 enzyme [6]. ACE2 is expressed in the lung, particularly in type 2 alveolar cells, and it appears to be the main gateway for the virus [7]. By this way, it causes lung damage. In addition to the lungs, ACE2 is also expressed in the myocardium, oesophagus and intestinal epithelium, vascular endothelium, bladder urothelial cells, and kidney proximal tubule. So, this is already shown as the reason for the course of Covid-19 infection towards multiorgan failure [8].

COVID-19 infection is much more aggressive and fatal in patients with comorbidities and the geriatric population. Studies show that advanced age is the most important determinant for mortality [9]. Epidemiological data reveal that the risk of death is significantly increased in people over 80 years of age compared to young people [10, 11]. At the same time, the frequency of cardiovascular disease (CVD) is also high in people who die due to COVID-19. In an epidemiological study involving 72.314 patients in China, 22.7% of fatal cases had a history of CVD [12]. In a study including seven hospitals in Spain and comparing 1139 COVID-19 positive patients with 11.390 healthy people, it was found that the CVD (odds ratio, OR, 1.98) and CVD risk factors (OR, 1.46) and comorbid diseases such as hypertension (HT) (OR, 1.27), chronic obstructive pulmonary disease (COPD) (OR, 1.35), diabetes mellitus (DM) (OR, 1.5) and heart failure (HF) (OR, 2.18) are more common in COVID-19 positive patients than in healthy control group [13]. Similarly, with the information we have obtained from “Severe Acute Respiratory Syndrome” (SARS) and “Middle East Respiratory Syndrome” (MERS) infections, the mortality rate is higher in patients with cardiovascular diseases. The prevalence of DM and CVD in SARS was determined to be 11% and 8% respectively, and the presence of these two comorbidities has been shown to increase the risk of death 12 times [14, 15]. In MERS, DM and HT were seen in approximately 50% of the cases, and CVD were seen in approximately 30% of the cases [5]. As a result, the most affected group and the group with the highest mortality rate are the elderly with cardiovascular diseases.

As the symptoms and signs of the disease were recognized, the importance of cardiovascular damage was understood and it attracted more attention [16]. COVID-19 affects the cardiovascular system in many ways. It increases morbidity and aggravates

myocardial damage and dysfunction in patients with accompanying cardiovascular diseases. The virus can affect the cardiovascular system and heart direct and/or indirect ways. Hemodynamic compromise, hypoxemia, inflammatory myocarditis, stress cardiomyopathy, microvascular dysfunction, or thrombosis due to hypercoagulability and systemic inflammation may impair the stabilization of coronary artery plaques [17]. In severe COVID-19 infection, the risk of type 2 myocardial infarction (MI) may increase by the need for increased cardiac output with hypoxia due to lung disease. Although the data on Covid-19 are still insufficient, studies are showing that pneumonia and influenza infection increase acute MI 6 times [18, 19].

HYPERTENSION

Considering that there are approximately 1.5 billion hypertensive patients in the world, it is not surprising that HT was the first co-morbid disease to be noted in articles on COVID-19 infection [17]. In a study conducted in the United States of America (USA), while 89.3% of 1482 patients hospitalized due to COVID-19 had at least one chronic disease, HT was the most common one with a frequency of 49.7% [20]. In the meta-analysis of four case-control studies including 1352 patients, HT was found to be the most common comorbidity and it was reported that the risk of the need for intensive care unit (OR, 2.54) increased in cases accompanied by HT [21]. In a retrospective cohort study in which acute respiratory distress syndrome (ARDS) and risk of death were analyzed in 201 COVID-19 positive patients, HT was found in 27.4% of patients who developed ARDS, while this rate was found as 13.7% in those who did not develop ARDS; however, a statistically significant difference could not be demonstrated [22]. In a multi-center study examining the impact of chronic diseases in 1590 COVID-19 positive patients in China, mortality was found higher in patients with HT (10.4%) compared to those without HT (1.7%) [23]. It has been demonstrated in many observational studies originating from China that mortality and morbidity increase in COVID-19 positive patients with HT [24, 25]. In the data from China and Italy, it has been shown that hypertensive patients constitute approximately 70% of the population, and progression to ARDS is significantly higher in patients with HT [26].

These have led to the discussions that the antihypertensive drugs that are effective through ACE, the cell entry protein of the virus, and increasing ACE2 [angiotensin 1 receptor blockade (ARB) and ACE inhibitors] may play a role in the pathogenesis of COVID-19 infection. However, these studies did not investigate the relationship between HT and mortality-morbidity in age-adjusted regression models. In addition, in these studies, HT is highly variable and mostly defined as being on antihypertensive treatment. Drug compliance and blood pressure control parameters were not mentioned.

The SARS-CoV-2 spike (S) protein uses the ACE2 receptor to enter the host cell, as in SARS and MERS [6]. The S protein binds to the catalytic domain of ACE2 with high affinity. The binding of the S protein to ACE2 triggers a conformational change in the S protein of the coronavirus and in this way, viral RNA enters the cell and infects the cell [27]. The concern that the treatment with ACE inhibitors or ARBs will increase viral binding and infection by causing tissue-level up-regulation of the ACE2 receptor in HT patients is the basis of the controversy [28]. Studies are showing increased ACE2 mRNA expression in the left ventricle

of normotensive Lewis rats and enalapril in rat heart tissue after treatment with Lisinopril and Losartan [29, 30]. Ishiyama et al. reported the increase of ACE2 mRNA levels in the coronary endothelium after the treatment with ARBs in their study with coronary artery ligation [31]. On the other hand, there are also experimental studies that have not shown a similar effect. In a study, after coronary artery ligation and treatment with ramipril, no increase in ACE2 mRNA compared to control was shown [32].

Also, Burchill et al. observed no increase in ACE2 protein in rat coronary endothelium after coronary artery ligation and treatment with valsartan, ramipril, or both [33]. The human studies showing ACE2 up-regulation with the renin-angiotensin aldosterone system (RAAS) are highly contradictory. In the study of Walters et al., no association was found in plasma ACE2 levels with the use of ACE inhibitors or ARBs [34]. Furuhashi et al. showed increased urinary ACE2 levels in patients with HT after using Olmesartan [35].

As can be seen from the current literature, the ACE2 receptor up-regulation hypothesis with RAAS blockers is based only on limited in-vitro and in-vivo animal experiments, and the studies in which this hypothesis cannot be demonstrated in humans and animals are also available in the literature.

In none of the accessible studies, there is no data on ACE2 up-regulation in respiratory epithelium and type 2 pneumocytes, the entrance gate used by SARS-CoV2 to infect the body. On the other hand, it has been shown in animal experiments that ACE2 transforms angiotensin 2 to angiotensin 1 - 7, and this vasodilatory effect occurring in this way can reduce lung damage in viral pneumonia [24]. Similarly, it has been suggested that ACE2, which is down-regulated by the SARS-CoV-2 surface spike protein, can be increased by RAAS blockade, thus antagonizing the effects of SARS-CoV-2 [36]. The guideline published by the American Heart Association and the American College of Cardiology (AHA/ACC) recommends the continuation of RAAS antagonists, which have proven useful in diseases such as heart failure, ischaemic heart disease, and HT, in COVID-19 patients [37]. In a study including seven hospitals in Spain, it was shown that there was no increase in the risk of hospitalization due to COVID-19 in patients using RAAS inhibitors, and there was no significant difference between long and short-term drugs use. One of the important findings of this study is that DM patients using RAAS inhibitors have a lower risk of hospitalization due to COVID-19 (OR 0.53, $p = 0.004$) [13].

Roffi et al. suggested that ARBs may be protective for COVID-19 depending on their mechanism of action [38]. However, since there is not enough evidence to support these hypotheses, it is not appropriate to use ACE inhibitors and ARBs as a potential treatment for COVID-19. As a result, if there is no contraindication such as hypotension or acute kidney damage, patients using ACE inhibitors or ARBs should continue their medication during COVID-19 infection.

CORONARY ARTERY DISEASE

It is known that the prevalence of coronary artery disease (CAD) among cardiovascular diseases varies depending on the society. For this reason, there are significant differences in the frequency of CAD among patients diagnosed with COVID-19. The studies about COVID-19 have also reported a wide range from 4.2 to 25% for CAD [39, 40]. These numbers are

much higher when considering patients treated in intensive care units [40]. In a large series of 72,314 people in China, the death rate was 2.3%, while the mortality rate over 80 years old was 14.8%. While 4.2% of all patients had a history of CAD, 22.7% of those who died had CAD [41].

ACE2, the cell-entry receptor of SARS-CoV-2, is also found in endothelial cells. Whether the vascular irregularities in COVID-19 infection are caused by the endothelial cell involvement of the virus or not is currently unclear but SARS-CoV-2 has been shown to infect human blood vessel organoids in-vitro [42]. Varga et al. demonstrated viral inclusion patterns in endothelial cells in an autopsy analysis of a 71-year-old male patient who died of COVID-19 and had CAD, HT, and kidney transplant, the recipient. This way, they found evidence of direct virus infection and widespread endothelial inflammation in the endothelial cell [43]. The vascular endothelium is an active paracrine, endocrine, and autocrine organ indispensable for regulating vascular tone and maintaining vascular homeostasis. Endothelial dysfunction is the main determinant of microvascular dysfunction by shifting the vascular balance to more vasoconstriction with organ ischemia, inflammation, and a pro-clotting state [44]. Thus, interest in treatments for stabilizing the endothelium has increased. Statins commonly used in the treatment of CAD are inhibitors of the inflammatory pathway MYD88 and have been shown to stabilize MYD88 at in-vitro and animal studies [43]. The instability of MYD88 has been associated with negative consequences in SARS-COV and MERS-COV infections, but this relationship has not been identified with SAR-COV-2. Statins may be useful in treating COVID-19 infection, but further studies are needed for a recommendation. It is also important for the patient to use statin therapy regularly, as COVID-19 is also a risk factor for acute cardiac damage.

Continuation of the drugs used in the routine treatment of CAD has been recommended as it is recommended in hypertensive patients. None of the medications we use in treatment such as acetylsalicylic acid, beta-blockers, statins, and nitrate have been associated with poor results in the management of COVID-19 infection.

Pulmonary involvement of COVID-19 infection can cause arterial hypoxia and acidosis, and this can result in myocardial dysfunction. Although there are no cardiac complaints due to myocardial damage and microvascular deterioration, an increase in cardiac biomarkers (troponin and natriuretic peptide) and nonspecific ECG changes can be observed [43]. Studies showing the SARS-CoV2 primarily attacking pericytes in the heart may explain the capillary endothelial cell dysfunction and an increase in cardiac damage markers [45]. COVID-19 infection may also be present with type 1 and type 2 myocardial infarction (MI) as a result of respiratory failure and exposure to hypoxia, especially in elderly patients, or COVID-19 may be tested positive in the course of MI.

It should be kept in mind that the patient considered to have the acute coronary syndrome in clinical and laboratory terms, should be questioned in terms of COVID-19 and tested for SARS-CoV2. When the intervention is to be performed, the patients are accepted as positive only if there is a suspicious contact history. Percutaneous coronary intervention may be preferred instead of coronary artery bypass graft surgery in suitable patients for revascularisation to reduce exposure. In addition, in low-risk ST-segment elevation myocardial infarction (STEMI), thrombolytic therapy can be considered instead of the invasive procedure [45]. A separate catheter laboratory for COVID-19 patients can also be beneficial for both the patient and the healthcare team.

COVID-19 can cause MI, myocarditis, or arrhythmia directly and indirectly. In addition, hydroxychloroquine and chloroquine used in the treatment of COVID-19 infection may cause prolongation of the QT distance, development of the atrioventricular block, sick sinus syndrome, and bundle branch block by making sodium/potassium/calcium channel blockade. Hydroxychloroquine and chloroquine are widely used in the world due to their antiviral activity as well as their anti-inflammatory activity, but there are some points to be careful about when using these drugs. These agents are relatively well tolerated but may cause rare and serious side effects (<10%) such as heart conduction system, hypoglycemia, neuropsychiatric effects, and retinopathy.

Monitoring the patient by electrocardiography is recommended especially in critically ill patients and in patients receiving concomitant agents that prolong the QT interval (such as macrolides, fluoroquinolones, amiodarone). Efficiency and side effects will be revealed better as the studies continue.

As the health system is overburdened due to the COVID-19 pandemic, neglecting the patients with CAD is a serious problem. In Hong Kong, Tam et al. showed that the rate of care for STEMI cases was seriously affected after COVID-19. In Hong Kong, the time for the ambulance to reach the patient after the call has increased from 80-90 minutes to 318 minutes on average [46].

In a study from Italy, they found that there was a 48.4% total decrease in STEMI and Non-ST segment elevation myocardial infarction (NSTEMI) cases taken to the catheter laboratory during the COVID-19 pandemic, a decrease of 26.5% in STEMIs and a 65% decrease in NSTEMIs compared to the same period of the previous year ($p < 0.001$). The mortality rate of STEMI increased significantly with the pandemic compared to the previous year (risk ratio (RR) = 3.3; $p < 0.001$) and there was a significant increase in complications (RR = 1.8; $p = 0.009$). This situation is a serious alarm finding for public health and should be emphasized [47]. The reasons for this situation can be caused by the patient or the healthcare system.

The most important reasons arising from the patient could be considered as disruptions in drug usage and health control, delaying hospitalization due to the fear of the virus.

Considering the reasons caused by the healthcare system, the home care system is not adequately provided, and a safe intervention system cannot be organized.

HEART FAILURE

Heart failure (HF) can be triggered by COVID-19 infection in patients with previously known or undiagnosed HF. In addition to the infection increases the workload of the heart, acute myocardial damage may develop due to events such as acute MI, stress cardiomyopathy, cytokine storm, and this way, heart failure may develop or the existing disease may be decompensated. It is not clear whether the underlying heart failure is exacerbated or a de novo HF is developing in COVID-19 positive patients [48]. In the study of Zhou et al., they retrospectively evaluated the patients presenting with COVID-19 and found that although HF was observed in 23% of the patients during the follow-up, HF ratio among people lost was 52% [49]. In a study where 799 patients in Wuhan were screened, heart failure was found in 49% of the patients who died and 3% of those who recovered [50].

In patients infected with COVID-19, the clinical picture is usually in the form of acute respiratory failure and may progress to ARDS with a ground-glass opacity in imaging. This clinical presentation is not much different from patients admitted to the hospital with acute HF [51]. Therefore, in patients presenting with acute pulmonary edema, heart-related causes alone, or mixed causes related to COVID-19 infection should also be considered. For differential diagnosis, bilateral multilobar ground-glass opacification with peripheral or posterior distribution mainly in the lower lobes is typical for COVID-19 infection in computed tomography of the chest. Atypical views such as superposed consolidated areas on ground-glass opacity can be seen in the elderly population. Findings starting from a single focus and progressing to bilateral lung involvement are in favor of infection. The use of cardiac biomarkers and, more often, echocardiography are effective in differentiating the clinical picture of infection and heart failure [52].

We do not have any conclusive evidence that will require the cessation of treatments that have proven effects on mortality such as ACE inhibitor, ARB, angiotensin receptor blocker-neprilysin inhibitor (ARNI), and mineralocorticoid receptor antagonist (MRA). In the treatment of HF, drug changes and discontinuation of drugs are not recommended, as in HT and CAD.

CONCLUSION

As a result, the group most affected by the epidemic and having the highest mortality rate are the elderly with known cardiovascular diseases. In the guideline published by the AHA/ACC, they recommended the continuation of RAAS antagonists proven to be beneficial in diseases such as heart failure, ischaemic heart disease, and hypertension in COVID-19 patients. As the health system is overburdened due to the increase in COVID-19 cases during the pandemic process, it resulted in ignoring the patients with CAD, and thus the death rate of patients with CAD during the pandemic process has increased and this is a serious problem.

Chapter 466

THE IMPACT OF THE COVID-19 PANDEMIC ON CANCER PATIENTS

Hande Turna^{*}, MD

Istanbul University- Cerrahpasa, Cerrahpasa Medical Faculty,
Department of Medical Oncology, Istanbul, Turkey

ABSTRACT

COVID-19 infection in patients with cancer is associated with a significantly increased risk of case fatality. Strategies to reduce the likelihood of infection and improve early identification in this immunocompromised patient population is crucial. Clinicians must balance the risks of delaying cancer treatments versus the risks for SARS-CoV-2 exposure and the potential increased adverse outcomes of COVID-19 infection in cancer patients. Physical distancing rules and contact limitations should be essential components of cancer care delivery. Mortality from COVID-19 in cancer patients appears to be principally driven by age, gender, and comorbidities such as diabetes and obesity. Likelihood of severe illness from COVID-19 is higher among patients with lung cancer and hematologic malignancies. There is no identified evidence that cancer patients on cytotoxic chemotherapy or other anticancer treatment are at an increased risk of mortality from COVID-19 disease compared with those not on active treatment. Anti-CD20 monoclonal antibodies causing B cell depletion and lymphopenia may contribute to the severity of COVID-19 infection. Treatment with immune checkpoint inhibitors may have the potential to alleviate inflammation in COVID-19 infection. In retrospective cohort studies there are conflicting results but there is no clear data for increasing the severity of the infection. The management of COVID-19 infection in cancer patients is generally the same as in the general population. Mild cases and asymptomatic infections can be managed conservatively at home. Agents used specifically for COVID-19 are reserved for patients with severe disease. Clinicians delivering cancer care should have discussions with their patients about goals of care and future care planning's.

INTRODUCTION

COVID-19 pandemic has a tremendous effect on daily life, economic conditions, and the health care system all over the world. This impact of the pandemic on health care of cancer patients is also very challenging because of the competitive risks of death from cancer versus death from infection, and the higher lethality of SARS-CoV-2 infection in immunocompromised hosts.
